**Abstract-** Achromatic Indices  $A(K_n)$  of complete graphs on  $n$  vertices are not known in general. It is known that  $A(K_{14}) \leq 44$ . In this paper we have tightened the upper bound of  $A(K_{14})$  to 43.

**Key Words-** Achromatic index, colouring of graphs, complete edge colouring, proper edge colouring.

## I. INTRODUCTION

A  $k$ -edge colouring of a simple graph  $G$  is assigning  $k$  colours to the edges of  $G$  so that no two adjacent edges receive same colours. If for each pair  $t_i$  &  $t_j$  of colours there exist adjacent edges with this colours then the colouring is said to be complete.<sup>[1]</sup> Let  $G$  be a simple graph. The achromatic index  $\psi^l(G)$  of a simple graph  $G$  is the maximum number of colours used in the edge colouring of  $G$  such that the colouring is complete. All though  $\psi^l(G)$  is known for some graphs but in general it is not known for arbitrary simple graphs. For Complete graph  $G$  of order  $n$ ,  $\psi^l(G)$  is denoted by  $A(K_n)$ . It is known that  $39 \leq A(K_{14}) \leq 44$  In this paper we are going to prove that  $A(K_{14}) \neq 44$

## II. PROOF

Suppose  $A(K_{14})=44$

Let  $C$  be the optimal colouring of  $A(K_{14})$  with 44 colours.

“Any colour in the optimal colouring  $C$  has atleast 2 edges of that colour in  $C$ ” we denote the above argument by \*

(If not, Suppose some colour  $i$  has only one edge in  $C$  then the number of distinct colours represented at the extremities of this edge are at the most  $12+12=24$

Any other colour apart from above 25 colours ( 24 + colour  $i$ ) can't be present in  $C$  as the adjacencies with colour  $i$  are exhausted hence  $C$  consist of at the most 25 colours which contradicts to the choice of  $C$ . Hence \*)

Now  $|E(K_{14})|=14C_2=91$

$C$  can have the following possible structures.

**Case i)** forty three colours with each colour with twice edges in  $C$  & one colour (say  $t$ ) with five edges.

Or

**Case ii)** forty two colours with each colour with twice edges in  $C$ , one colour (say  $c_1$ ) with three edges & one colour (say  $c_2$ ) with four edges.

Or

**Caseiii)** forty one colours with two edges of each colour, three colours (say  $t_1, t_2, t_3$ ) with three edges each.

[Note: Any other combination fails to give the combination  $A(K_{14})=44$  &  $|E(K_{14})|=14C_2=91$  & each colour appearing at least twice in  $C$ ]

Before discussing the above cases, we will prove that if  $C$  contains the following structure for some colour  $i$  having exactly two edges of the colour  $i$  in  $C$  then  $A(K_{14}) \leq 43$  Suppose colour  $i$  has exactly two edges in  $C$  & for some colours  $j, k$  the following position is appearing in  $K_{14}$

(Numbers on edges represent colours throughout this paper.)

The number of distinct colours at the extremities of the edges coloured  $i$  apart from the colours  $j, k$  are at the most  $10+10+10+10=40$

Any other colour apart from above 43 colours (40+ colours  $i, j, k$ )

can't be present in  $C$  as the adjacencies with colour  $i$  are exhausted hence  $C$  consist of at the most 43 colours which contradicts to the choice of  $C$ .

The above position we will denote by “PP”.

Now consider the **case i**

Apart from 10 extremities of colour  $t$ , the any of the remaining 4 vertices has 13 colours incident with it & these 13 colours (WLG say  $1, 2, \dots, 13$ ) have exactly two edges in  $C$  (i.e exactly two edges are colored 1, exactly two edges are coloured 2,  $\dots$ , exactly two edges are coloured 13) WLG we arrive at the following situation.

Some pair of vertices must be joined to each other coloured as 1. W.L.G.  $V_2V_3$  be coloured as 1.

Now neither of the colours from 2 to 13 can be incident with  $V_2$  or  $V_3$  because if 2 is incident with  $V_2$  or 3 is incident with  $V_3$  will contradict to the fact C is proper edge colouring of  $K_{14}$ . If colour  $c$  ( $3 \leq c \leq 13$ ) is incident with  $V_2$  then "PP" appears as shown below.

Similarly if colour  $c$  (either  $c=2$  or  $4 \leq c \leq 13$ ) is incident with  $V_3$  then "PP" appears. Similarly we can argue for the remaining vertices,

The vertices from  $V_1$  to  $V_{13}$  can be joined pair wise by edges & can accommodate at the most 6 colours from the colours 1, 2, ..., 13 leaving no choice for the second edges of the remaining 7 colours. Therefore case i is discarded.

**Case ii)** Colours  $c_1$  &  $c_2$  together have 7 edges. If all of them are disjoint then it contradicts to the fact that C is complete colouring of  $K_{14}$ . hence  $\exists$  a vertex at which  $c_1$  &  $c_2$  are adjacent to each other once so  $\exists$  a vertex at which neither  $c_1$  nor  $c_2$  are incident with it & hence  $v$  has 13 colours incident with it & these 13 colours (WLG say 1, 2, ..., 13) have exactly two edges in C. So the case becomes similar to case i hence we discard case ii.

**Case iii)** If  $\exists$  a vertex as in the case i then we arrive at contradiction. Hence  $\nexists$  a vertex as in the case i

If at every vertex at least two of  $t_1, t_2, t_3$  are incident then Let H be the subgraph of  $K_{14}$  having edges coloured by  $t_1, t_2, t_3$  therefore  $|E(H)|=9$  &  $\deg_H V \geq 2$  for all vertices  $V \in V(K_{14})$

Now  $2|E(H)|=18$

$\therefore 18 = \sum \deg_H V_i$  for  $i=1$  to 14

But  $\sum \deg_H V_i \geq 2 \times 14 = 28$

$\therefore 18 \geq 28$  which is a contradiction.

$\therefore \exists$  a vertex (wlg say  $V_{14}$ ) such that exactly one of the colours  $t_1$  or  $t_2$  or  $t_3$  (wlg say  $t_1$ ) is incident with it. In general we arrive at the following position.

Now we will think of second edges of the colours 1 to 12.

As discuss in the case i, vertices  $V_1, V_2, \dots, V_{12}$  are pair wise joined & can be coloured with at most 6 colours from the colours 1 to 12 hence at least one of the colours from the colours 1 to 12 is incident with  $V_{13}$

Suppose  $q$  edges are of the type  $V_{13}V_j$  where  $1 \leq j \leq 12$  & are coloured with some of  $q$  colours from 1, 2, ..., 12.

$\therefore$  the remaining  $12-q$  vertices can accommodate at the most  $(12-q)/2$  colours from the remaining  $12-q$  colours

(at most  $(12-q)/2$  comes from the discussion of case i)

$\therefore q + (12-q)/2 = 12$

$\therefore q = 12$

$\therefore V_1V_{13}, V_2V_{13}, \dots, V_{11}V_{13}, V_{12}V_{13}$  are coloured using the colours 1, 2, ..., 12.

WLG  $V_{12}V_{13}$  is coloured with 1.

$\therefore$  The number of distinct colours adjacent to colour 1 in C are at the most

$$13 \text{ (namely } 1, 2, \dots, 12, t_1) + 12 \text{ (namely } V_1V_2, V_1V_3, \dots, V_1V_{12}) + 10 \text{ (namely } V_{12}V_2, V_{12}V_3, \dots, V_{12}V_{13}) = 35 \text{ colours}$$

Any other colour apart from above 36 colours (35+ colour 1)

Can't be present in C as the adjacencies with colour 1 are exhausted hence C consist of at the most 36 colours

which contradicts to the choice of C.

### III. CONCLUSION

$\nexists$  an complete edge colouring of  $K_{14}$  with 44 colours.

$\therefore A(K_{14}) \leq 43$
