**Abstract:** Graph theory provides the basis for many network analysis techniques. Basic graph theory concepts are very general and can be applied to a wide variety of network problems such as topological design, routing reliability analysis, and network capacity. Specific examples demonstrate that graph theory is a practical tool for solving network and distributed system problems.

**Keywords:** Adjacency matrix, Incidence matrix, reliability.

## INTRODUCTION

Any network problem can be represented by graph and graph can be represented by two different ways inside a computer, namely by using the adjacency matrix or the incidence matrix of a graph.

1 **Adjacency matrix:** If a graph  $G$  has  $n$  vertices, listed as  $v_1, v_2, \dots, v_n$ . The adjacency matrix of  $G$ , with respect to this particular listing of the  $n$  vertices of  $G$ , is the  $n \times n$  matrix  $A(G) = (A_{ij})$  where the  $(i, j)$ th entry  $A_{ij}$  is the number of edges from  $v_i$  to the vertex  $v_j$ . The following figure 1 shows a graph  $G$  with vertices listed as  $v_1, \dots, v_4$  and its adjacency matrix  $A(G)$  with respect to this listing. Figure 1: A graph and its adjacency matrix

$A(G)$ :  $4 \times 4$  matrix

	v1	v2	v3	v4
v1	1	1	0	1
v2	1	0	1	0
v3	0	1	0	2
v4	1	0	2	0

Here in  $A(G)$  we have  $A_{ij} = A_{ji}$  for each  $i$  and  $j$ . A matrix with this property is called symmetric. Also note that if  $G$  has no loops then all the entries of the main diagonal of  $A(G)$  are 0, while if  $G$  has no parallel edges then the entries of  $A(G)$  are either 0 or 1.

2 **Incidence matrix:** Suppose that  $G$  has  $n$  vertices, listed as  $v_1, v_2, \dots, v_n$  and  $t$  edges, listed as  $e_1, e_2, \dots, e_t$ . The incidence matrix of  $G$ , with respect to these particular listings of the vertices and edges of  $G$ , is the  $n \times t$  matrix  $M(G) = (m_{ij})$  where the vertex  $v_i$  is incidence with the edge  $e_j$  i.e.,

$$M_{ij} = \begin{cases} 0 & \text{if } v_i \text{ is not end of } e_j \\ 1 & \text{if } v_i \text{ is an end of the non-loop } e_j \\ 2 & \text{if } v_i \text{ is an end of the loop } e_j \end{cases}$$

The following figure 2 shows a graph G, with four vertices  $v_1, \dots, v_4$  and six edges  $e_1, \dots, e_6$  and its incidence matrix  $M(G)$  with respect to these listings of the vertices and edges.

Figure 2: A graph and its incidence matrix

$M(G)$ : A  $4 \times 6$  matrix

	e1	e2	e3	e4	e5	e6
v1	2	1	0	0	0	1
v2	0	1	1	0	0	0
v3	0	0	1	1	1	0
v4	0	0	0	1	1	1
