# Strong limiting regions of hypertension vector sequences of order statistics 

N. Vadiraja ${ }^{1}$, H. Vishnu Hebbar ${ }^{2}$<br>Assistant Professor - Statistics, Department of Community Medicine, Mysore Medical College and Research Institute Mysuru, Karnataka, India ${ }^{1}$, Retd. Professor, DOS in Statistics, Manasagangotri, University of Mysore, Mysuru ${ }^{2}$

- Short title: Limit Points of vector sequences
- AMS classification: Primary 60F15; secondary 60G17

#### Abstract

This paper finds a limiting region for the patient's hypertension behavior based on several values above the cut off value of blood pressure taking together, by properly normalizing the vector sequences comprising of moving maxima $\left(Y_{k(n)}\right)$, moving second maxima $\left(S_{k(n)}\right), \ldots$, moving $K^{\text {th }}$ maxima $K_{k(n)}$, $K$ being the $K^{\text {th }}$ order statistics, using Borel Cantelli lemma, which is meaningful in taking the decision on hypertension for treatment and so on. However, for ease of computation, results are proved for $Y_{k(n)}$ and $S_{k(n)}$, under certain conditions on $F$ and $k(n)$. The results are just stated for $K$ order statistics.

Keywords: Almost sure limit set; Moving maxima; Moving second maxima; Vector sequence

## 1. Introduction

Under clinical trial set up in medical field, to study the hypertensive patient, he must be under observation for several days. Patient's hypertension behavior based on several values above the cut off value of blood pressure taking together is meaningful in taking the decision on hypertension for treatment and so on. Thus the hypertension values on the jth day are independent. This scenario demands a new model for the limiting behavior by considering the $\mathrm{K}^{\text {th }}$ order statistics of hypertension values of a patient. When observations are more, leaving first few observations do not matter a much. Thus the $\mathrm{K}^{\text {th }}$ order statistics values of a patient on the $\mathrm{j}^{\text {th }}$ day are a moving order statistics. As a result, this paper finds a limiting region for above scenario by properly normalizing the vector sequences comprising of moving maxima $\left(\mathrm{Y}_{\mathrm{k}(\mathrm{n})}\right)$, moving second maxima $\left(\mathrm{S}_{\mathrm{k}(\mathrm{n})}\right.$ ), ,., moving $\mathrm{M}^{\text {th }}$ maxima $\mathrm{M}_{\mathrm{k}(\mathrm{n})}$, M being the $\mathrm{M}^{\text {th }}$ order statistics, using Borel Cantelli lemma. However, for ease of computation, results are proved for $\mathrm{Y}_{\mathrm{k}(\mathrm{n})}$ and $\mathrm{S}_{\mathrm{k}(\mathrm{n})}$ for the following set up. The results are stated for M moving order statistics.

Let $\left\{X_{n}, n \geq 1\right\}$ be a sequence of independent identically distributed random variables (i.i.d.r.v) with common distribution function (d.f) F. Define, moving maxima $Y_{k(n)}=\max \left(X_{n+1}, X_{n+2}, \ldots, X_{n+k(n)}\right)$ where $k(n)$ is a sequence of positive integers, $2 \leq \mathrm{k}(\mathrm{n}) \leq \mathrm{n}$. The term moving maxima is due to Rothmann and Russo (1991). In the light of the concept of moving maxima, define moving second maxima as $S_{k(n)}=\operatorname{second} \max \left(X_{n+1}, X_{n+2}\right.$, $\left.\ldots ., X_{n+k(n)}\right)$ and moving third maxima as $T_{k(n)}=T h i r d \max \left(X_{n+1}, X_{n+2}, \ldots, X_{n+k(n)}\right)$ for the same $k(n)$ and so on. For $\mathrm{k}(\mathrm{n}) \Xi \mathrm{n}, \mathrm{Y}_{\mathrm{k}(\mathrm{n})} \Xi \mathrm{Y}_{\mathrm{n}}, \mathrm{S}_{\mathrm{k}(\mathrm{n})} \Xi \mathrm{S}_{\mathrm{n}}, \mathrm{T}_{\mathrm{k}(\mathrm{n})} \Xi \mathrm{T}_{\mathrm{n}}$ and so on.

De Hann and Hordijk (1972) have obtained lim sup and lim inf of properly normalized $Y_{n}$, under the following assumptions on F .

Assumption $\mathbf{A ( C )}$. F has positive derivative $\mathrm{F}^{\prime}(\mathrm{x})$ for all sufficiently large x and $\lim _{n \rightarrow \infty} \frac{g(x)}{x}=c, 0<c<\infty$ where $g(x)=\frac{1-F(x)}{F^{\prime}(x)} \log _{2}\left(\frac{1}{1-F(x)}\right)$ with $\log _{2} \mathrm{u}=\log \log \mathrm{u}$.
Assumption B. F is twice differentiable and $\mathrm{F}^{\prime}(\mathrm{x})$ is positive for all sufficiently large x with $\lim _{n \rightarrow \infty} g^{\prime}(x)=0$.
Hebbar and Vadiraja(1996-97, 97) generalized the Gut's (1990) result using moving maxima and
Borel_Cantelli (B_C) lemma approach for more general K(n):

$$
\begin{equation*}
\mathrm{K}(\mathrm{n}) \text { is non-decreasing } \tag{1.1}
\end{equation*}
$$

$$
\begin{equation*}
\operatorname{Sup}[k(n+1)-k(n)] \leq \mu(\text { finite }) \tag{1.2}
\end{equation*}
$$

and

$$
\begin{equation*}
k(n)=\left[\frac{n}{(\log n)^{t(n)}}\right] \text { where } \mathrm{t}(\mathrm{n}) \rightarrow \infty \text { as } \mathrm{n} \rightarrow \infty \tag{1.3}
\end{equation*}
$$

Next, define $b_{n}$ through $1-F\left(b_{n}\right)=n^{-1}$ and they made
Assumption C. $1-F\left(b_{n} x\right)=\frac{(\log n)^{\gamma(1-\beta(x))}}{n^{\beta(x)}} a_{n}(x), x>0$ where $\gamma$ is a constant, $\beta(\mathrm{x})$ is strictly increasing and positive, $\lim _{n \rightarrow \infty} a_{n}(x)=\theta(x)>0$.

For the standard normal distribution, Assumption C holds with $\beta(\mathrm{x})=\mathrm{x}^{2}, \mathrm{a}_{\mathrm{n}}(\mathrm{x})=\mathrm{c}_{\mathrm{n}}(\mathrm{x}) \theta(\mathrm{x}), \quad \theta(x)=\left[\frac{(4 \pi)^{x^{2} / 2}}{x \sqrt{2}}\right]$,
$\mathrm{c}_{\mathrm{n}}(\mathrm{x}) \rightarrow 1$ as $\mathrm{n} \rightarrow \infty, \quad \gamma=-1 / 2$, using the fact that $1-F(x) \sim\left[\frac{e^{-x^{2} / 2}}{x \sqrt{2 \pi}}\right]$ as
$\mathrm{n} \rightarrow \infty$ and for the unit exponential distribution $\beta(\mathrm{x})=\mathrm{x}, \mathrm{a}_{\mathrm{n}}(\mathrm{x})=1, \gamma=0$.

When $\mathrm{c}=\infty$, the assumption is as follows.
Assumption D. Let the support F be $[0, \infty)$ and let $h(x)=\frac{g(x)}{x}$.

$$
\begin{equation*}
1-F\left(b_{n} x^{h\left(b_{n}\right)}\right)=\frac{(\log n)^{\gamma\left(n, x^{h\left(b_{n}\right)}\right)}}{n}, \forall x>0 \tag{1.4}
\end{equation*}
$$

where $\lim _{n \rightarrow \infty} r\left(n, x^{h\left(b_{n}\right)}\right)=-\log x$.
Under Assumption D, the following example holds good.
Example 1. $\quad 1-\mathrm{F}(\mathrm{x})=1 / \mathrm{x}, \mathrm{x} \geq 1$. Then, $\mathrm{b}_{\mathrm{n}}=\mathrm{n}, \mathrm{h}(\mathrm{x})=\log \log \mathrm{x}$ and hence $r\left(n, x^{h\left(b_{n}\right)}\right)=-\log x$.
Example 2. $\quad 1-F(x)=1 / \log x, x \geq e$. Then, $b_{n}=e^{-n}, h(x)=\log x \log \log x$ and hence
$1-F\left(b_{n} x^{h\left(b_{n}\right)}\right)=\frac{1}{n(1+\log x \log \log x)}$ which does not satisfy Assumption C.

Throughout, $\delta_{\mathrm{i}}$ 's, $\mathrm{i}=1,2, .$. are sufficiently small positive constants. Now the results are stated below.

Theorem 1. Under Assumption $A(C)$, the almost sure limit set of the vector sequence
$\left\{Y_{k(n)} / b_{n}, S_{k(n)} / b_{n}\right\} n \geq 1$, coincides with the region $S_{1}=\left\{(x, y): e^{-p c} \leq x \leq e^{c}, e^{-p c} \leq y \leq e^{c}, x \geq y\right.$,
$\left.x y \leq e^{(1-p) c}\right\} 0 \leq p<\infty$.
Theorem 2. Under the conditions of Theorem 1 but with $\mathrm{p}=\infty$, the almost sure limit set of the vector sequence $\{$
$\left.\mathrm{Y}_{\mathrm{k}(\mathrm{n})} / \mathrm{b}_{\mathrm{n}}\right\} \mathrm{n} \geq 1$, coincides with the region $\mathrm{S}_{2}=\left[0, \mathrm{e}^{\mathrm{c}}\right]$, provided there exists a strictly decreasing sequence $\mathrm{q}_{\mathrm{n}} \sim$
$k(n) / n$ and either
i. $\quad k(n) \geq \gamma \log n \mathrm{kn}) \geq \gamma \log \mathrm{n}$ for some $\gamma>0$ and
ii. $\quad 1<\mathrm{k}(\mathrm{n}) \leq \gamma \log \mathrm{n}$

Theorem 3. Under the condition of Theorem 1 but with $p=\infty, \lim _{n \rightarrow \infty}\left(\mathrm{~S}_{\mathrm{k}(\mathrm{n})} / \mathrm{b}_{\mathrm{n}}\right)=0 \ldots$ a.s.

Theorem4. Under Assumption B, the almost sure limit set of the vector sequence
$\left\{\left(\mathrm{Y}_{\mathrm{k}(\mathrm{n})}-\mathrm{b}_{\mathrm{n}}\right) / \mathrm{d}_{\mathrm{n}},\left(\mathrm{S}_{\mathrm{k}(\mathrm{n})}-\mathrm{b}_{\mathrm{n}}\right) / \mathrm{d}_{\mathrm{n}}\right\} \mathrm{n} \geq 1$, coincides with the region $\mathrm{S}_{3}=\{(\mathrm{x}, \mathrm{y}):-\mathrm{p} \leq \mathrm{x} \leq 1,-\mathrm{p} \leq \mathrm{y} \leq 1, \mathrm{x} \geq \mathrm{y}$,
$\mathrm{x}+\mathrm{y} \leq(1-\mathrm{p})\} 0 \leq \mathrm{p}<\infty$, where $\mathrm{d}_{\mathrm{n}}=\mathrm{f}\left(\mathrm{b}_{\mathrm{n}}\right) \log _{2} \mathrm{n}$ with $\mathrm{f}(\mathrm{x})=(1-\mathrm{F}(\mathrm{x})) \mathrm{F}^{\prime}(\mathrm{x})$.
When $\mathrm{p}=\infty$, Theorem 4 can be refined as
Theorem5. Under Assumption B and Assumption C, the almost sure limit set of the vector sequence $\left\{Y_{k(n)} / b_{n}\right.$,
$\left.\mathrm{S}_{\mathrm{k}(\mathrm{n})} / \mathrm{b}_{\mathrm{n}}\right\} \mathrm{n} \geq 1$, coincides with the region $\mathrm{S}_{4}=\{(\mathrm{x}, \mathrm{y}): \mathrm{d} \leq \mathrm{x} \leq 1, \mathrm{~d} \leq \mathrm{y} \leq 1, \mathrm{x} \geq \mathrm{y}$,
$\beta(\mathrm{x})+\beta(\mathrm{y}) \leq 1+\Delta\}$, where d satisfies $\mathrm{d}=\beta^{-1}(\Delta)$ for all $\epsilon>0$ with $\Delta=\lim _{\mathrm{n}_{\rightarrow}}[\operatorname{logk}(\mathrm{n}) / \operatorname{logn}]$
Now, the corollaries follow
Corollary 1. Under the conditions of Theorem1, the almost sure limit set of the sequence
i. $\quad\left\{Y_{k(n)} / b_{n}\right\} n \geq 1$, coincides with the region $S_{5}=\left[e^{-p c}, e^{c}\right]$
ii. $\quad\left\{S_{k(n)} / b_{n}\right\} n \geq 1$, coincides with the region $S_{6}=\left[e^{-p c}, e^{(1-p) c / 2}\right], 0 \leq p<\infty$.

Corollary 2. Under the conditions of Theorem4, the almost sure limit set of the sequence
i. $\quad\left\{\left(\mathrm{Y}_{\mathrm{k}(\mathrm{n})}-\mathrm{b}_{\mathrm{n}}\right) / \mathrm{d}_{\mathrm{n}}\right\} \mathrm{n} \geq 1$, coincides with $\mathrm{S}_{7}=[-\mathrm{p}, 1-\mathrm{p}]$
ii. $\quad\left\{\left(\mathrm{S}_{\mathrm{k}(\mathrm{n})}-\mathrm{b}_{\mathrm{n}}\right) / \mathrm{d}_{\mathrm{n}}\right\} \mathrm{n} \geq 1$, coincides with $\mathrm{S}_{8}=[-\mathrm{p},(1-\mathrm{p}) / 2], 0 \leq \mathrm{p}<\infty$.

Corollary 3. Under the conditions of Theorem5 but with $\mathrm{p}=\infty$, the almost sure limit set of the sequence
i. $\quad\left\{\mathrm{Y}_{\mathrm{k}(\mathrm{n})} / \mathrm{b}_{\mathrm{n}}\right\} \mathrm{n} \geq 1$, coincides with the region $\mathrm{S}_{9}=[\mathrm{d}, 1]$
ii. $\quad\left\{\mathrm{S}_{\mathrm{k}(\mathrm{n})} / \mathrm{b}_{\mathrm{n}}\right\} \mathrm{n} \geq 1$, coincides with the region $\mathrm{S}_{10}=\left[\mathrm{d}, \beta^{-1}((1+\Delta) / 2)\right]$

Remark: Let $Y_{k(n)}^{*}=\max \left(\mathrm{X}_{\mathrm{n}-\mathrm{k}(\mathrm{n})+1}, \mathrm{X}_{\mathrm{n}-\mathrm{k}(\mathrm{n})+2}, \ldots, \mathrm{X}_{\mathrm{n}}\right)$ and $S_{k(n)}^{*}=\operatorname{second} \max \left(\mathrm{X}_{\mathrm{n}-\mathrm{k}(\mathrm{n})+1}, \mathrm{X}_{\mathrm{n}-\mathrm{k}(\mathrm{n})+2}, \ldots ., \mathrm{X}_{\mathrm{n}}\right)$ are the backward moving maxima and backward moving second maxima respectively. Then the above results hold good.

## 2. Proofs.

The proof of Theorem 1 is built up through the following lemmas.
Lemma 1.2. (Ortega and Wschebor 1984, Lemma 1).
Let $\left(A_{n}\right) n \geq 1$, be a sequence of events on a probability space. If

$$
\begin{equation*}
\sum_{n=1}^{\infty} P\left(A_{n}\right)=\infty \tag{2.1}
\end{equation*}
$$

and

$$
\begin{equation*}
\liminf _{n \rightarrow \infty} \frac{\sum_{1 \leq i<j \leq n} \sum\left(P\left(A_{i} \cap A_{j}\right)-P\left(A_{i}\right) P\left(A_{j}\right)\right)}{\left(\sum_{i=1}^{n} P\left(A_{i}\right)\right)^{2}} \leq 0 \tag{2.2}
\end{equation*}
$$

then $\mathrm{P}\left(\begin{array}{ll}\mathrm{A}_{\mathrm{n}} & \text { i.o }\end{array}\right)=1$.
Lemma 2.2. ( De Haan and Hordijk 1972, pp 1190-92)

$$
\begin{equation*}
1-F\left(b_{n} x\right)=\frac{(\log n)^{\gamma(n, x)}}{n}, \forall x>0 \tag{2.3}
\end{equation*}
$$

where

$$
\begin{equation*}
\lim _{n \rightarrow \infty} r(n, x)=\frac{-\log x}{c} \text { under Assumption A } \tag{2.4}
\end{equation*}
$$

and

$$
\begin{equation*}
\lim _{n \rightarrow \infty} r(n, x)=-x \text { under Assumption B } \tag{2.5}
\end{equation*}
$$

where $b_{n} x$ in (2.3) is replaced by $d_{n} x+b_{n}$.
Lemma 3.2. For every $\epsilon>0, x>y>e^{-p c}$ and $x y<e^{(1-p) c}$,

$$
\begin{equation*}
P\left(Y_{k\left(l_{i}\right)}>(x+\varepsilon) b_{l_{i}}, S_{k\left(l_{i}\right)}>y b_{l_{i}} i . o\right)=0 \tag{2.6}
\end{equation*}
$$

and

$$
\begin{equation*}
P\left(Y_{k\left(l_{i}\right)}>x b_{l_{i}}, S_{k\left(l_{i}\right)}>(y+\varepsilon) b_{l_{i}} \text { i.o }\right)=0 \tag{7.2}
\end{equation*}
$$

where $l_{i}=\left\lfloor e^{i^{\theta}}\right\rfloor$, and $\theta=\left[2 p+\frac{\log x y}{c}+\frac{\log (1+\varepsilon)}{4 c}\right]^{-1}$

Proof. Notice that by (3.2)

$$
\begin{align*}
& P\left(Y_{k\left(l_{i}\right)}>(x+\varepsilon) b_{l_{i}}, S_{k\left(l_{i}\right)}>y b_{l_{i}}\right) \\
= & P\left(Y_{k\left(l_{i}\right)}>(x+\varepsilon) b_{l_{i}}\right)-P\left(Y_{k\left(l_{i}\right)}>(x+\varepsilon) b_{l_{i}}, S_{k\left(l_{i}\right)} \leq y b_{l_{i}}\right) \\
= & 1-F^{k\left(l_{i}\right)}\left((x+\varepsilon) b_{l_{i}}\right)-k\left(l_{i}\right) F^{k\left(l_{i}\right)-1}\left(y b_{l_{i}}\right) \cdot\left(1-F\left((x+\varepsilon) b_{l_{i}}\right)\right) \\
= & \frac{(1+0(1))}{2} k\left(l_{i}\right) \cdot\left(k\left(l_{i}\right)-1\right)\left(1-F\left((x+\varepsilon) b_{l_{i}}\right)\right) \cdot\left(1-F\left(y b_{l_{i}}\right)\right) \\
\leq & \text { Const. } k^{2}\left(l_{i}\right) \cdot\left(1-F\left((x+\varepsilon) b_{l_{i}}\right)\right) \cdot\left(1-F\left(y b_{l_{i}}\right)\right) \tag{8.2}
\end{align*}
$$

for all i large, since,

$$
\begin{aligned}
& k\left(l_{i}\right) \cdot\left(1-F\left((x+\varepsilon) b_{l_{i}}\right)\right) \rightarrow 0, \text { for } x>e^{-p c} \\
& k\left(l_{i}\right) \cdot\left(1-F\left(y b_{l_{i}}\right)\right) \rightarrow 0, \text { for } y>e^{-p c}
\end{aligned}
$$

and

$$
\left[\frac{\left(1-F\left((x+\varepsilon) b_{l_{i}}\right)\right)}{\left(1-F\left(y b_{l_{i}}\right)\right)}\right] \rightarrow 0, \text { for } x>y
$$

$$
=\text { Const. }\left(\frac{k\left(l_{i}\right)}{l_{i}}\right)^{2} \cdot\left(\log l_{i}\right)^{r\left(l_{i}, x+\varepsilon\right)+r\left(l_{i}, y\right)}=\mathrm{E}_{\mathrm{i}} \text {, (say) }
$$

Now, as $\mathrm{i} \rightarrow \infty$, in view of (3.1) and (4.2),
$\left(2 t\left(l_{i}\right)-r\left(l_{i}, x+\varepsilon\right)+r\left(l_{i}, y\right)\right) \rightarrow\left(2 p+\frac{\log x y}{c}+\frac{\log (1+\varepsilon)}{c}\right)$
Hence, for every $€>0$ and for I large, we have
$\left(\log l_{i}\right)^{-\left(2 p++\frac{\log x y}{c}+\frac{3 \log (1+\varepsilon)}{2 c}\right)}<E_{i}<\left(\log l_{i}\right)^{-\left(2 p+\frac{\log x y}{c}+\frac{\log (1+\varepsilon)}{2 c}\right)}$
$\theta .\left(2 t\left(l_{i}\right)-r\left(l_{i}, x+\varepsilon\right)+r\left(l_{i}, y\right)\right)>\theta .\left(2 p+\frac{\log x y}{c}+\frac{\log (1+\varepsilon)}{2 c}\right)=1+\delta_{1}$
where $\delta_{1}=\left[\frac{7 \theta \log (l+\varepsilon)}{4 c}\right]>0$
by (2.9).

Then, in view of (8.2) and (10.2),
$\sum P\left(Y_{k\left(l_{i}\right)}>(x+\varepsilon) b_{l_{i}}, S_{k\left(l_{i}\right)}>y b_{l_{i}}\right)<\infty$
Accordingly, by B_C lemma, (6.2) follows.
The Proof of (7.2) is similar.
Lemma 4.2. For $e^{-p c}<x<e^{c}, e^{-p c}<y<e^{c}, x>y$ and $x y<e^{(1-p) c}$,
$P\left(Y_{k\left(l_{i}\right)}>x b_{i}, S_{k\left(l_{i}\right)}>y b_{l_{i}} i . o\right)=1$
Proof. Similar to that at (8.2) and then at (10.2),

$$
\begin{aligned}
& P\left(Y_{k\left(l_{i}\right)}>x b_{i}, S_{k\left(l_{l}\right)}>y b_{i}\right) \\
& =\text { Const. } k\left(l_{i}\right) \cdot\left(k\left(l_{i}\right)-1\right) \cdot\left(1-F\left(x b_{i}\right)\right) \cdot\left(1-F\left(y b_{i}\right)\right)
\end{aligned}
$$

$=$ Const. $i^{-\theta \cdot\left(2 t\left(l_{i}\right)-r\left(l_{i}, x\right)-r\left(l_{i}, y\right)\right)}$
$=$ Const. $i^{-\left(1+\delta_{2}\right)}$
where $\quad \delta_{2}=\left[\frac{\theta \log (1+\varepsilon)}{12 c}\right]>0 \quad$ for every $\mathrm{C}>0$ and i large.
To establish the claim made, it is sufficient to show the events $P\left(Y_{k\left(l_{i}\right)}>x b_{l_{i}}, S_{k\left(l_{i}\right)}>y b_{l_{i}}\right), \mathrm{i} \geq 1$ are independent for all i large.

$$
\begin{equation*}
l_{i}-k\left(l_{i}\right)+1-l_{i-1}=l_{i}\left[1-\frac{k\left(l_{i}\right)}{l_{i}}+\frac{1}{l_{i}}-\frac{l_{i-1}}{l_{i}}\right] \tag{12.2}
\end{equation*}
$$

Now observe that
i. $\quad \operatorname{By}(3.1),\left(\log l_{i}\right)^{-(p+\delta)}<\frac{k\left(l_{i}\right)}{l_{i}}<\left(\log l_{i}\right)^{-(p-\delta)}$, for $\delta>0$, i large.
ii. For $\theta>1, \frac{l_{i-1}}{l_{i}} \rightarrow 0$ as $\mathrm{i} \rightarrow \infty$
iii. For $\theta \leq 1, \frac{l_{i-1}}{l_{i}} \rightarrow 1,1-\frac{l_{i-1}}{l_{i}} \sim h i^{\theta-1}$ as $\mathrm{i} \rightarrow \infty$ where h is a positive constant.

Hence, whenever $\theta>1$, i.e. $\left(2 p+\frac{\log x y}{c}\right)<1$,
R.H.S $(12.2)$ is $\sim 1_{i}$ as $i \rightarrow \infty$. Further for $(1+p)^{-1}<\theta \leq 1$, the expression inside the square bracket of $(12.2)$ is $\sim h^{(\theta-1)}$
as $\mathrm{i} \rightarrow \infty$, since $i^{(1-\theta)} \cdot \frac{k\left(l_{i}\right)}{l_{i}} \rightarrow 0$.
Thus, for $\theta>(1+p)^{-1}$, i.e. for $\mathrm{xy}\left\langle\mathrm{e}^{(1-\mathrm{p}) \mathrm{c}}\right.$,
R.H.S(12.2) tends to $\infty$ as $\mathrm{i} \rightarrow \infty$.

Thus, the events under consideration are independent, for all i large.

Lemma 5.2. For all $\mathrm{x} \geq \mathrm{e}^{-\mathrm{pc}}, \mathrm{y} \geq \mathrm{e}^{-\mathrm{pc}}$ with $\mathrm{xy}>\mathrm{e}^{(1-\mathrm{p}) \mathrm{c}}$ and for every $€>0$,

$$
P\left(Y_{k(n)}>(x+\varepsilon) b_{n}, S_{k(n)}>(y+\varepsilon) b_{n} i . o\right)=0
$$

Proof. Define the events

$$
\begin{aligned}
& A_{n}=\left\{Y_{k(n)}>(x+\varepsilon) b_{n}, S_{k(n)}>(y+\varepsilon) b_{n}\right\} \text { and } \\
& B_{i}=\left\{Y_{k(n)}>(x+\varepsilon) b_{i}, S_{k(n)}>(y+\varepsilon) b_{i} \text { forat least one } n \in\left[n_{i}, n_{i+1}\right)\right\}
\end{aligned}
$$

where $n_{i}=\left[e^{i^{\theta}}\right], \mathrm{i} \geq 1, \theta=\left[2 p+\frac{\log x y}{c}\right]^{-1}$
Notice that

$$
\begin{equation*}
P\left(A_{n} . \text {.i.o in } \mathrm{n}\right) \leq P\left(B_{i} . \text {.i.o in } \mathrm{i}\right) \tag{13.2}
\end{equation*}
$$

But, $\mathrm{P}\left(\mathrm{B}_{\mathrm{i}}\right) \leq$
$P\left(\max \left(X_{\left.n_{i}-k\left(n_{i}\right)+1, \cdots, X_{n_{i+1}}\right)>(x+\varepsilon) b_{n_{i}} \cdot \operatorname{secondmax}\left(X_{\left.\left.n_{i}-k\left(n_{i}\right)+1, \cdots, X_{n_{i+1}}\right)>(y+\varepsilon) b_{n_{i}}\right)}\right), ~\left(B_{1}\right)}\right)\right.$
$\leq\left(\frac{n_{i+1}-n_{i}+k\left(n_{i}\right)-1}{n_{i}}\right)^{2} \cdot\left(\log n_{i}\right)^{r\left(n_{i}, x+\varepsilon\right)+r\left(n_{i}, y+\varepsilon\right)}$
by (3.2).

But, for $\theta<(1+\mathrm{p})^{-1}$, i.e. for $\mathrm{xy}>\mathrm{e}^{(1-\mathrm{p}) \mathrm{c}}$ and in view of (3.1),

$$
\begin{equation*}
\left(\frac{n_{i+1}-n_{i}+k\left(n_{i}\right)-1}{n_{i}}\right) \leq \frac{\text { Const } .}{i^{\theta \cdot p}} \tag{15.2}
\end{equation*}
$$

In view of (15.2) and (4.2), (14.2) becomes

$$
\leq \frac{\text { Const }}{i^{\theta \cdot\left(2 p+\frac{\log x y}{c}\right)+2 \theta\left(\frac{\log (1+\varepsilon / x)+\log (1+\varepsilon / y)}{c}\right)}} \leq \frac{\text { Const }}{i^{1+\delta_{3}}}
$$

for every $€>0$ and i large, where $\delta_{3}=\left[\frac{2 \theta \log (1+\varepsilon / x)+\log (1+\varepsilon / y)}{c}\right]>0$.
By appealing to B_C lemma, $P\left(B_{i}\right.$ i.o $)=0$.

This completes the proof of our lemma via (13.2).

Lemma 6.2. For every $\Theta>0$ and $\mathrm{x}_{0}=\mathrm{e}^{-\mathrm{pc}}(1-\mathcal{\epsilon})$

$$
P\left(S_{k(n)}>x_{0} b_{n} i . d\right)=0
$$

Proof. This is accomplished by showing

$$
\begin{equation*}
P\left(S_{k(n)} \leq x_{0} b_{n}\right) \rightarrow 0 \tag{16.2}
\end{equation*}
$$

and

$$
\begin{equation*}
\sum_{n=1}^{\infty} P\left(S_{k(n)} \leq x_{0} b_{n} \text { and } S_{k(n+1)}>x_{0} b_{n+1}\right)<\infty \tag{17.2}
\end{equation*}
$$

Note that,

$$
\begin{align*}
P\left(S_{k(n)}\right. & \left.\leq x_{0} b_{n}\right)=P\left(S_{k(n)} \leq x_{0} b_{n}, Y_{k(n)} \leq x_{0} b_{n}\right)+P\left(S_{k(n)} \leq x_{0} b_{n}, Y_{k(n)}>x_{0} b_{n}\right) \\
& =P\left(Y_{k(n)} \leq x_{0} b_{n}\right)+P\left(S_{k(n)} \leq x_{0} b_{n}, Y_{k(n)}>x_{0} b_{n}\right) \\
& =F^{k(n)}\left(x_{0} b_{n}\right)+k(n) F^{k(n)-1}\left(x_{0} b_{n}\right) \cdot\left(1-F\left(x_{0} b_{n}\right) \cdot\right) \\
& =E_{n} F^{k(n)-1}\left(x_{0} b_{n}\right) \cdot\left(1+\frac{F\left(x_{0} b_{n}\right)}{E_{n}}\right) \\
& \leq E_{n} F^{k(n)-1}\left(x_{0} b_{n}\right) \cdot\left(1+\frac{1}{E_{n}}\right) \tag{18.2}
\end{align*}
$$

where $E_{n}=k(n) .\left(1-F\left(x_{0} b_{n}\right)\right)$.
By (3.1), (3.2), (4.2) we have for every $€>0$ and for some $\mathrm{a}>0$

$$
\begin{equation*}
(\log n)^{a-\varepsilon}<E_{n}<(\log n)^{a+\varepsilon} \text { for all large n. } \tag{19.2}
\end{equation*}
$$

Fix $\mathrm{M}>0$, so that $\mathrm{M}(\mathrm{a}-\mathrm{C})-(\mathrm{a}-\mathrm{C})>1+\delta_{4}, \delta_{4}>0$.
By (3.2) and (19.2),
R.H.S $(2.18) \leq(1+o(1)) e^{-(\log n)^{a-\varepsilon}}(\log n)^{a+\varepsilon} \leq(1+o(1))(\log n)^{\left(1+\delta_{4}\right)}$

Thus, in view of (20.2) and (18.2), (16.2) holds.
Now, since $b_{n}$ is non decreasing, notice that

$$
\begin{align*}
& P\left(S_{k(n)} \leq x_{0} b_{n} \text { and } S_{k(n+1)}>x_{0} b_{n+1}\right) \\
& \leq P\left(S_{k(n)} \leq x_{0} b_{n}, Y_{k(n)} \leq x_{0} b_{n}, S_{k(n+1)}>x_{0} b_{n}\right)+P\left(S_{k(n)} \leq x_{0} b_{n}, Y_{k(n)}>x_{0} b_{n}, S_{k(n+1)}>x_{0} b_{n}\right) \tag{21.2}
\end{align*}
$$

Case(i). When $n-k(n+1)+2 \geq n-k(n)+1$
R.H.S(2.21) $\leq k(n) F^{k(n)-1}\left(x_{0} b_{n}\right) .\left(1-F\left(x_{0} b_{n}\right) .\right)^{2}$

By (3.2),(4.2) and (19.2) and on similar lines to (20.2), for all n large and $\delta_{5}>0$,
R.H.S(22.2) $\leq \frac{\text { Const }}{n(\log n)^{1+\delta_{5}}}$

Thus, in view of (21.2) and (23.2), (17.2) holds.

Case(ii). When $n-k(n+1)+2<n-k(n)+1$, the arrangement of observation is as follows.

$$
X_{n-k(n+1)+2}, \ldots \ldots, X_{n-k(n)}, X_{n-k(n)+1} \ldots, X_{n}, X_{n+1}
$$

Thus, R.H.S (2.21)

$$
\begin{aligned}
& =\mathrm{P}\left(\text { At least two among } \mathrm{X}_{\mathrm{n}-\mathrm{k}(\mathrm{n}+1)+2}, \ldots \ldots, \mathrm{X}_{\mathrm{n}-\mathrm{k}(\mathrm{n})}, \mathrm{X}_{\mathrm{n}+1}>\mathrm{x}_{0} \mathrm{~b}_{\mathrm{n}}\right) . \mathrm{P}\left(\text { Each of } \mathrm{X}_{\mathrm{n}-\mathrm{k}(\mathrm{n})+1} \ldots, \mathrm{X}_{\mathrm{n}} \text { is } \leq \mathrm{x}_{0} \mathrm{~b}_{\mathrm{n}}\right)+\mathrm{P}(\mathrm{At} \\
& \\
& \text { least one among } \left.\mathrm{X}_{\mathrm{n}-\mathrm{k}(\mathrm{n}+1)+2}, \ldots \ldots, \mathrm{X}_{\mathrm{n}-\mathrm{k}(\mathrm{n})}, \mathrm{X}_{\mathrm{n}+1}>\mathrm{x}_{0} \mathrm{~b}_{\mathrm{n}}\right) . \mathrm{P}(\text { Exactly one among } \\
& \\
& \left.\mathrm{X}_{\mathrm{n}-\mathrm{k}(\mathrm{n})+1} \ldots ., \mathrm{X}_{\mathrm{n}}>\mathrm{x}_{0} \mathrm{~b}_{\mathrm{n}} \text { and Remaining }(\mathrm{k}(\mathrm{n})-1) \text { observations are } \leq \mathrm{x}_{0} \mathrm{~b}_{\mathrm{n}}\right) \\
& =\left\{1-\mathrm{P}\left(\text { At the most one among } \mathrm{X}_{\mathrm{n}-\mathrm{k}(\mathrm{n}+1)+2}, \ldots \ldots, \mathrm{X}_{\mathrm{n}-\mathrm{k}(\mathrm{n})}, \mathrm{X}_{\mathrm{n}+1} \leq \mathrm{x}_{0} \mathrm{~b}_{\mathrm{n}}\right)\right\} . F^{k(n)}\left(x_{0} b_{n}\right)+ \\
& \\
& \left\{1-\mathrm{P}\left(\mathrm{All}(\mathrm{k}(\mathrm{n}+1)-\mathrm{k}(\mathrm{n})) \text { observations are } \leq \mathrm{x}_{0} \mathrm{~b}_{\mathrm{n}}\right)\right\} . k(n) F^{k(n)-1}\left(x_{0} b_{n}\right) \cdot\left[1-F\left(x_{0} b_{n}\right)\right] \\
& =F^{k(n)}\left(x_{0} b_{n}\right) \cdot\left[1-F^{k(n+1)-k(n)}\left(x_{0} b_{n}\right)-(k(n+1)-k(n)) \cdot\left(1-F\left(x_{0} b_{n}\right)\right) \cdot F^{k(n+1)-k(n)-1}\left(x_{0} b_{n}\right)+\right. \\
& \\
& k(n) F^{k(n)}\left(x_{0} b_{n}\right) \cdot\left[1-F\left(x_{0} b_{n}\right)\right) \cdot\left[1-F^{k(n+1)-k(n)}\left(x_{0} b_{n}\right)\right] \\
& \leq F^{k(n)-1}\left(x_{0} b_{n}\right) \cdot\left[1-F^{k(n+1)-k(n)}\left(x_{0} b_{n}\right)-(k(n+1)-k(n)) \cdot\left(1-F\left(x_{0} b_{n}\right)\right) \cdot F^{k(n+1)-k(n)-1}\left(x_{0} b_{n}\right)\right. \\
& \left.\quad+k(n)\left(1-F\left(x_{0} b_{n}\right)\right)\left(1-F^{k(n+1)-k(n)}\left(x_{0} b_{n}\right)\right)\right]
\end{aligned}
$$

Using the fact that $\mathrm{e}^{-\mathrm{t}}=1=\mathrm{t}(1+\mathrm{o}(1))$, where $\mathrm{t}=\left(1-\mathrm{F}\left(\mathrm{x}_{0} \mathrm{~b}_{\mathrm{n}}\right)\right) \rightarrow 0$, as $\mathrm{n} \rightarrow \infty$,

$$
\begin{aligned}
& \leq F^{k(n)-1}\left(x_{0} b_{n}\right)\left[(k(n+1)-k(n)) \cdot\left(1-F\left(x_{0} b_{n}\right)\right) \cdot(1+o(1))+k(n)(k(n+1)-k(n)) \cdot\left(1-F\left(x_{0} b_{n}\right)\right)^{2} \cdot(1+o(1))\right] \\
& \leq(1+o(1)) \cdot k(n)(k(n+1)-k(n)) \cdot F^{k(n)-1}\left(x_{0} b_{n}\right) \cdot\left(1-F\left(x_{0} b_{n}\right)\right)^{2} .
\end{aligned}
$$

in view of (18.2), for all large $n$.
On similar lines to case (i), (17.2) holds.

Lemma 7.2 . No point in the region
$\left\{e^{-p c} \leq x \leq e^{c}, e^{-p c} \leq y \leq e^{c}\right.$ with $\left.x<y.\right\}$ is a limit point of $\left\{\frac{Y_{k(n)}}{b_{n}}, \frac{S_{k(n)}}{b_{n}}\right\} n \geq 1$.

Proof. For any subsequence $\left\{\mathrm{n}_{1}\right\}$, since $Y_{k\left(n_{l}\right)}>S_{k\left(n_{l}\right)}$ a.s., we should have $\mathrm{x} \geq \mathrm{y}$ which is a contradiction. Hence the lemma.

The following lemma is trivial , hence the details are omitted.
Lemma 8.2 . For every $€>0$ and $\mathrm{x}_{0}=\mathrm{e}^{-\mathrm{pc}}$
$P\left(Y_{k(n)}<\left(x_{0}-\varepsilon\right) b_{n}\right.$ i.o $)=0$
Proof of Theorem 1. $\mathrm{S}_{1}$ is a required limit set by lemmas 5.2, 6.2, 7.2 and 8.2 . We conclude with the fact that the limit set is necessarily closed and from the lemmas 3.2 and 4.2. This completes the proof of Theorem 1.

Proof of Theorem 2. On similar lines to Theorem 1 and hence details are skipped.
When $\mathrm{p}=\infty$, the results for $\mathrm{S}_{\mathrm{k}(\mathrm{n})}$ are as follows.
Lemma $9.2 \limsup _{n \rightarrow \infty} \frac{S_{k(n)}}{b_{n}} \leq 0 \quad$ a.s
Proof. This is accomplished by showing for every $€>0$,
$P\left(S_{k(n)}>\varepsilon b_{n} i . O\right)=0$

This is in turn will follow, when we show
$P\left(S_{k(n)}>\delta b_{n}\right) \rightarrow 0$ as $\mathrm{n} \rightarrow \infty$
and $\sum_{n=1}^{\infty} P\left(S_{k(n)} \leq \varepsilon b_{n}\right.$ and. $\left.S_{k(n+1)}>\varepsilon b_{n+1}\right)<\infty$
Next, (25.2) and (26.2) are accomplished on similar lines to lemma 6.2 and hence through (24.2), lemma 9.2 is achieved.

Lemma 10.2. $\liminf _{n \rightarrow \infty} \frac{S_{k(n)}}{b_{n}} \geq 0 \quad$ a.s
Proof. This is trivial and hence the details are omitted.
Proof of Theorem 3. We conclude that the limit exists for $S_{k(n)}$ from lemmas 9.2 and 10.2. Hence the proof of Theorem.

Due to Theorem 3, the almost sure limit set of vector sequence $\left\{\frac{Y_{k(n)}}{b_{n}}, \frac{S_{k(n)}}{b_{n}}\right\} n \geq 1$, shrinks to the interval $\left[0, e^{c}\right]$ on the x axis.

Proof of Theorem 4. Similar to Theorem 1, choosing $l_{i}=\left\lfloor e^{i^{\theta}}\right\rfloor$, and $\theta=\left[2 p+x+y+\frac{\varepsilon}{2}\right]^{-1}$.
Proof of Theorem 5. Similar to Theorem 1, but with $l_{i}=\left[i^{\theta}\right]$ where $\theta=\left[\beta(x)+\beta(y)-2 \Delta+\frac{\varepsilon}{2}\right]^{-1}$
Following are the results for Mth order statistics.
Theorem 6. Under Assumption $A(C)$, the almost sure limit set of the vector sequence
$\left\{Y_{k(n)} / b_{n}, S_{k(n)} / b_{n} \ldots, M_{k(n)} / b_{n}\right\} n \geq 1$, coincides with the region $S_{1}=\left\{(x, y, \ldots, m): e^{-p c} \leq x \leq e^{c}, e^{-p c} \leq y \leq e^{c}, \ldots ., e^{-}\right.$ $\left.{ }^{\mathrm{pc}} \leq \mathrm{m} \leq \mathrm{e}^{\mathrm{c}}, \mathrm{x} \geq \mathrm{y} \geq \ldots \geq \mathrm{m}, \mathrm{xy} \ldots . \mathrm{m} \leq \mathrm{e}^{(1-\mathrm{p}) \mathrm{c}}\right\} 0 \leq \mathrm{p}<\infty$.

Theorem 7. Under the conditions of Theorem 1 but with $\mathrm{p}=\infty$, the almost sure limit set of the vector sequence \{ $\left.Y_{k(n)} / b_{n}\right\} n \geq 1$, coincides with the region $S_{2}=\left[0, e^{c}\right]$, provided there exists a strictly decreasing sequence $q_{n} \sim$ $\mathrm{k}(\mathrm{n}) / \mathrm{n}$ and either
i. $\quad k(n) \geq \gamma \log n \mathrm{kn}) \geq \gamma \log \mathrm{n}$ for some $\gamma>0$ and
ii. $\quad 1<\mathrm{k}(\mathrm{n}) \leq \gamma \log \mathrm{n}$
and
$\lim _{n \rightarrow \infty}\left(S_{k(n)} / b_{n}\right)=0, \ldots, \lim _{n_{\rightarrow}}\left(\mathrm{M}_{\mathrm{k}(\mathrm{n})} / \mathrm{b}_{\mathrm{n}}\right)=0 \ldots$ a.s.

Theorem 8. Under Assumption B, the almost sure limit set of the vector sequence
$\left\{\left(Y_{k(n)}-b_{n}\right) / d_{n},\left(S_{k(n)}-b_{n}\right) / d_{n}, \ldots,\left(M_{k(n)}-b_{n}\right) / d_{n}\right\} n \geq 1$, coincides with the region $S_{3}=\{(x, y, . . m):-p \leq x \leq 1,-p \leq y \leq$ $1, \ldots, p \leq m \leq 1, x \geq y \geq \ldots \geq m$,
$\mathrm{x}+\mathrm{y}+\ldots+\mathrm{m} \leq(1-\mathrm{p})\} 0 \leq \mathrm{p}<\infty$, where $\mathrm{d}_{\mathrm{n}}=\mathrm{f}\left(\mathrm{b}_{\mathrm{n}}\right) \log _{2} \mathrm{n}$ with $\mathrm{f}(\mathrm{x})=(1-\mathrm{F}(\mathrm{x})) \mathrm{F}^{\prime}(\mathrm{x})$.
When $\mathrm{p}=\infty$, Theorem 4 can be refined as
Theorem9. Under Assumption B and Assumption C, the almost sure limit set of the vector sequence $\left\{\mathrm{Y}_{\mathrm{k}(\mathrm{n})} / \mathrm{b}_{\mathrm{n}}\right.$, $\left.\mathrm{S}_{\mathrm{k}(\mathrm{n})} / \mathrm{b}_{\mathrm{n}} \ldots, \mathrm{M}_{\mathrm{k}(\mathrm{n})} / \mathrm{b}_{\mathrm{n}}\right\} \mathrm{n} \geq 1, \quad$ coincides with the region $\mathrm{S}_{4}=\{(\mathrm{x}, \mathrm{y}, \ldots, \mathrm{k}): \mathrm{d} \leq \mathrm{x} \leq 1, \mathrm{~d} \leq \mathrm{y} \leq 1, \ldots, \mathrm{~d} \leq \mathrm{m} \leq 1, \mathrm{x} \geq \mathrm{y} \geq$ $\ldots, \geq \mathrm{m}$,
$\beta(\mathrm{x})+\beta(\mathrm{y})+\ldots+\beta(\mathrm{m}) \leq 1+\Delta\}$, where d satisfies $\mathrm{d}=\beta^{-1}(\Delta)$ for all $\epsilon>0$ with $\Delta=\lim _{\mathrm{n}_{\mathrm{n}}}[\operatorname{logk}(\mathrm{n}) / \operatorname{logn}]$
