**Abstract** - In this paper, the theory of  $Q_m$ -normal families of meromorphic functions of one complex variable is promoted to bicomplex meromorphic functions. To study the properties of  $Q_m$ -normal families in the bicomplex case, we have extended the definition of  $C_m$ -point and  $C_m$ -sequences from one complex variable to the bicomplex case and obtained its important results. Many results of  $Q_m$ -normal families of one complex variable case are seen to hold in the bicomplex case. Moreover, the necessary and sufficient condition for  $Q_m$ -normality in the bicomplex case is obtained.

**Keywords** - Bicomplex numbers, Bi-complex meromorphic functions, Normal families,  $Q_m$ -normal families,  $C_m$ -point and  $C_m$ -sequences.

## 1. Introduction

The foundation of bicomplex analysis can be traced back to the pioneering work of William Kingdon Clifford [17] in the late 19th century, who introduced the concept of bicomplex numbers as an extension of complex numbers. Clifford's contributions laid the groundwork for further developments in this field. In the early 20th century, the field witnessed significant advancements with the seminal works of Georg Frobenius [18] and Elie Cartan, who made notable contributions to the theory of bicomplex numbers and their algebraic properties. In the latter half of the 20th century, J.D. Riley made significant contributions to bicomplex analysis, particularly through his work titled "Contributions to the Theory of Functions of a Bicomplex Variable". The dawn of the 21st century witnessed renewed interest in bicomplex analysis, with researchers such as K.S. Charak, D. Roohan and Narinder Sharma [7,8,11] delving into the study of normal families of bicomplex holomorphic and meromorphic functions. Their work, along with contributions from others in the field, has led to significant advancements in understanding the geometric, analytic and computational aspects of these families. Today, the exploration of  $Q_m$ -normal families continues to be a vibrant area of research, with scholars building upon the foundational works of their predecessors to unravel the intricacies of bicomplex analysis and its applications in various domains. Through collaborative efforts and interdisciplinary approaches, researchers aim to further expand the frontiers of knowledge in this fascinating field.

In recent years, the exploration of  $Q_m$ -normal families of bicomplex meromorphic functions has emerged as a captivating frontier within the domain of bicomplex analysis. Building upon foundational works by prominent researchers such as Riley, Charak, Sharma, and others, significant strides have been made in unraveling the intricate properties and behaviors inherent to these families. Today, the exploration of  $Q_m$ -normal families continues to be a vibrant area of research, with scholars building upon the foundational works of their predecessors to unravel the intricacies of bicomplex analysis and its applications in various domains. Through collaborative efforts and interdisciplinary approaches, researchers aim to further expand the frontiers of knowledge in this fascinating field. In recent years, the exploration of  $Q_m$ -normal families of bicomplex meromorphic functions has emerged as a captivating frontier within the domain of bicomplex analysis. Building upon foundational works by prominent researchers such as Riley, Charak, Sharma, and others, significant strides have been made in unraveling the intricate properties and behaviors inherent to these families. The seminal contributions of Riley, dating back to the early 2000s, laid the groundwork for understanding the fundamental characteristics of bicomplex meromorphic functions and their relevance within the framework of  $Q_m$ -normal families. Subsequent research endeavors by K. S Charak and Narinder Sharma, among others, have further deepened the understanding, shedding light on the geometric and analytic aspects of these families. Through their collective efforts, researchers have illuminated the rich interplay between bicomplex analysis and the theory of  $Q_m$ -normal families, offering valuable insights into the geometric, analytic, and computational facets of this intriguing area of study. As we embark on this journey of exploration, we stand poised to unearth new vistas of knowledge and innovation guided by the pioneering works of these esteemed scholars. The exploration of bicomplex analysis, spanning from the theory of bicomplex numbers to the study of

$Q_m$ -normal families, has been a journey marked by significant contributions from various researchers across different periods. The concept of  $Q_m$ -normal families [4] arises from the desire to understand the behavior of functions in the bicomplex plane that possess distinctive normalization properties.  $Q_m$ -normality extends the classical notion of normality, introducing a more nuanced criterion for the convergence of certain families of functions. This extension becomes particularly intriguing when applied to bicomplex analysis, where the interplay of real and imaginary components introduces complexities that diverge from the traditional complex setting.

Moreover, the study of  $Q_m$ -normality contributes to the broader understanding of function theory in the bicomplex domain, shedding light on the behavior of functions that transcend the classical confines of complex analysis.  $Q_m$ -normal families in the bicomplex setting lie in their potential applications in various branches of mathematics and physics. These families provide a versatile framework for modeling phenomena that involve multiple variables and complex interactions. In this study, we explore the details of  $Q_m$ -normal families [4] in the context of the bicomplex plane. Our objectives are to research the basic characteristics of these families, as well as their possible applications and linkages with other classes of functions. By undertaking this study, we seek to advance the understanding of function theory in bicomplex analysis and contribute valuable insights to the broader mathematical community.

## 2. Preliminaries

Here, we introduce some of the basic definitions and results of the theory of bicomplex numbers, which are required for defining new definitions and results. Corrado Segre, in 1892, while studying special algebras, published a paper [14] in which he carried his research on an infinite family of algebra whose elements are called bicomplex numbers, tricomplex numbers, ... n-complex numbers. Bicomplex numbers, also known as tetra-numbers, are defined as follows:

$\mathbb{T} = \{z_1 + z_2 i_2 : z_1, z_2 \in C(i_1)\}$ , where the imaginary units  $i_1, i_2$  and  $j$  are governed by the rules:

$$i_1^2 = i_2^2 = -1, j^2 = 1 \quad \text{and} \quad i_1 i_2 = i_2 i_1 = j, \quad i_1 j = j i_1 = -i_2, \quad i_2 j = j i_2 = -i$$

Thus, one can easily see that multiplication of two bicomplex numbers is commutative. In fact, bicomplex numbers have a unique character that forms commutative algebra but not division algebra. It is convenient to write the set of bicomplex numbers as  $\mathbb{T} = \{x_0 + x_1 i_1 + x_2 i_2 + x_3 j : x_0, x_1, x_2, x_3 \in \mathbb{R}\}$ . It is also important to know that every bicomplex number has the following unique idempotent representation:

$$z_1 + z_2 i_2 = (z_1 - z_2 i_1) e_1 + (z_1 + z_2 i_1) e_2$$

Where  $e_1 = \frac{(1+j)}{2}$  and  $e_2 = \frac{(1-j)}{2}$ . This idempotent representation of bicomplex numbers is very useful because addition, multiplication, and division can be done term-by-term. The operation addition on  $\mathbb{T}$  can be defined by the function  $\oplus: \mathbb{T} \times \mathbb{T} \rightarrow \mathbb{T}$  as:

$$(x_0 + x_1 i_1 + x_2 i_2 + x_3 j, y_0 + y_1 i_1 + y_2 i_2 + y_3 j) = (x_0 + y_0) + (x_1 + y_1) i_1 + (x_2 + y_2) i_2 + (x_3 + y_3) j$$

The operation scalar multiplication on  $\mathbb{T}$  is defined by the function  $\odot: \mathbb{R} \times \mathbb{T} \rightarrow \mathbb{T}$  as:

$$(a, x_0 + x_1 i_1 + x_2 i_2 + x_3 j) = (ax_0 + ax_1 i_1 + ax_2 i_2 + ax_3 j). \text{ Thus, the structure } (\mathbb{T}, \oplus, \odot) \text{ forms a linear space. Therefore,}$$

the norm on  $\mathbb{T}$  is defined by the function  $\|\cdot\|: \mathbb{T} \rightarrow \mathbb{R}_{\geq 0}$  as  $\|x_0 + x_1 i_1 + x_2 i_2 + x_3 j\| = (x_0^2 + x_1^2 + x_2^2 + x_3^2)^{\frac{1}{2}}$ .

Thus, the structure  $(\mathbb{T}, \oplus, \odot, \|\cdot\|)$  forms a normed linear space.

### 2.1. Conjugation Operations in $\mathbb{T}$

The concept of complex conjugation plays a pivotal role in both the algebraic and geometric aspects of  $C$  complex functions as well as in the analysis of them. Conjugation operations in the bicomplex plane provide essential tools for analyzing and understanding the structure and behavior of bicomplex holomorphic functions, extending many classical concepts from complex analysis to the more intricate bicomplex setting. In the context of bicomplex numbers, there exist three conjugation operations, each playing a crucial role in understanding the properties and behaviors of bicomplex holomorphic functions. It's not surprising that there exist three distinct conjugations in  $\mathbb{T}$ . The three types of conjugations on  $\mathbb{T}$  are defined as follows:

#### 2.1.1. Complex Conjugation

For a bicomplex number  $w = z_1 + jz_2$ , where  $z_1 = x_1 + yi$  and  $z_2 = u_1 + vi$  with  $i^2 = -1$ , the complex conjugate is defined as

$$w^* = \bar{z}_1 + i_2 \bar{z}_2 = (x - yi) + i_2(u - vi).$$

This operation is performed by taking the complex conjugate of each component  $z_1$  and  $z_2$

### 2.1.2. Bicomplex Conjugation

Another important conjugation operation in the bicomplex context is the bicomplex conjugate.  $w = z_1 + i_2 z_2$  it is defined as:  $w^* = z_1 - i_2 z_2$

This conjugation changes the sign of the  $i_2$ -component.

### 2.1.3. Mixed Conjugation

Combining both the complex and bicomplex conjugations, we get the mixed conjugate:

$$w^\oplus = \bar{z}_1 - j\bar{z}_2 = (x - yi) - i_2(u - vi).$$

This operation involves taking the complex conjugate of each component and changing the sign of the  $i_2$ -component.

## 2.2. Cartesian Set and Disc in $\mathbb{T}$

### 2.2.1. Definition

The Cartesian set  $X$  determined by  $X_1$  and  $X_2$ , which are subsets of  $C(i_1)$ , is defined as follows:  
 $X_1 \times_e X_2 = \{w = z_1 + z_2 i_2 \in T : P_1(w) \in X_1, P_2(w) \in X_2\}$ , Where  $P_1$  and  $P_2$  are the projections on  $X$ .

It can be easily seen that if  $X_1$  and  $X_2$  are domains in  $C(i_1)$ , then  $X_1 \times_e X_2$  it is also a domain in  $\mathbb{T}$ . Then a way to construct some "disc" (of center 0) in  $\mathbb{T}$  is to take  $\mathbb{T}$ -Cartesian product of two discs (of center 0) in  $C(i_1)$ . Let  $r, r_1, r_2$  denote the real numbers such that  $r > 0, r_1 > 0$  and  $r_2 > 0$ . Also, let  $A_1 = \{z_1 - z_2 i_1 \in T : z_1, z_2 \in C(i_1)\}$  and  $A_2 = \{z_1 + z_2 i_1 \in T : z_1, z_2 \in C(i_1)\}$ . Then, the open disc with the Centre

$a = a_1 + a_2 i_1 + a_3 i_2 + a_4 i_1 i_2 = \alpha + i_2 \beta$  of radius  $r_1$  and  $r_2$  is defined as follows [1]:

$$D(a; r_1, r_2) = B^1(\alpha - i_1 \beta, r_1) \times_e B^1(\alpha + i_1 \beta, r_2) = \{w_1 e_1 + w_2 e_2 : |w_1 - (\alpha - i\beta)| < r_1, |w_2 - (\alpha + i\beta)| < r_2\}.$$

**Theorem 2.2.2:** Every  $z_1 + z_2 i_2 \in \mathbb{T}$  is uniquely represented as  $z_1 + z_2 i_2 = P_1(z_1 + z_2 i_2) e_1 + P_2(z_1 + z_2 i_2) e_2$

**Proof:** Let  $Z = z_1 + z_2 i_2$  be any bicomplex number. We want to show that

$$Z = P_1(Z) e_1 + P_2(Z) e_2, \text{ where } P_1(Z) = z_1 + z_2 i_1 \text{ and } P_2(Z) = z_1 - z_2 i_1.$$

We know that every bicomplex number can be expressed as:

$$Z = z_1 + z_2 i_2 = (z_1 - z_2 i_1) e_1 + (z_1 + z_2 i_1) e_2, \text{ where } e_1 = (1 + i_2 i_1)/2 \text{ and } e_2 = (1 - i_2 i_1)/2.$$

Therefore, from (1.2), we have  $Z = z_1 + z_2 i_2 = (z_1 - z_2 i_1) e_1 + (z_1 + z_2 i_1) e_2$ .

Let  $P_1, P_2 : \mathbb{T} \rightarrow C(i_1)$  be the two projections such that:  $P_1(Z) = z_1 + z_2 i_1$  and  $P_2(Z) = z_1 - z_2 i_1$

Using the above projections and idempotent basis,  $Z$  can be written as  $Z = P_1(Z) e_1 + P_2(Z) e_2$

$$\begin{aligned} \text{Therefore, } P_1(Z) e_1 + P_2(Z) e_2 &= (z_1 + z_2 i_1)(1 + i_2 i_1)/2 + (z_1 - z_2 i_1)(1 - i_2 i_1)/2 \\ &\rightarrow P_1(Z) e_1 + P_2(Z) e_2 = 1/2[(z_1 + z_2 i_1)(1 + i_2 i_1) + (z_1 - z_2 i_1)(1 - i_2 i_1)] \\ &\rightarrow P_1(Z) e_1 + P_2(Z) e_2 = 1/2[z_1(1 + i_2 i_1) + z_2 i_1(1 + i_2 i_1) + z_1(1 - i_2 i_1) - z_2 i_1(1 - i_2 i_1)] \end{aligned}$$

Combining like terms and using  $i_1^2 = 1$  and  $i_2 i_1 = -i_1 i_2$ , we get:

$$P_1(Z) e_1 + P_2(Z) e_2 = 1/2[2z_1 + z_2 i_1 + z_2 i_1 i_2 i_1 - z_2 i_1 + z_2 i_1 i_2 i_1]$$

On further simplification, we get:  $P_1(Z) e_1 + P_2(Z) e_2 = 1/2[2z_1 + 2z_2 i_2]$ . Since  $i_1 i_2 i_1 = -i_2$ , therefore

$$P_1(Z) e_1 + P_2(Z) e_2 = z_1 + z_2 i_2$$

Thus, we have shown that every bicomplex number  $Z = z_1 + z_2 i_2$  can be uniquely expressed as:

$$Z = P_1(Z) e_1 + P_2(Z) e_2, \text{ where } P_1(Z) = z_1 + z_2 i_1 \text{ and } P_2(Z) = z_1 - z_2 i_1.$$

This representation of bicomplex numbers is advantageous because it allows for straightforward addition, multiplication, and division term-by-term. Furthermore, it aids in understanding the structure of functions of a bicomplex variable, as we will explore in the next section.

**2.3. Basic definition and properties of bicomplex meromorphic functions**

It is generally known[15] that in the complex plane, a function  $f$  is meromorphic in an open set  $U$  if and only if  $f$  is a quotient  $g/h$  of two functions that are holomorphic in  $U$  where  $h$  is not identically zero in any component of  $U$ . This formulation serves as the foundation for how a bicomplex meromorphic function is defined. Based on this definition, K.S Charak et al; defined a bicomplex meromorphic function as follows.

**Definition 2.3.1:** [11] If a function  $f$  is a quotient of two functions  $g/h$  that are bicomplex holomorphic in  $\Omega$  and  $h$  is not identically in the null-cone in any component of  $\Omega$ , then  $f$  is said to be a bicomplex meromorphic in the open set  $\Omega \subset \mathbb{T}$ .

**Theorem 2.3.2:** [11] Let  $f: \Omega \subseteq \mathbb{T} \rightarrow \mathbb{T}$  be a bicomplex meromorphic function on the open set  $\Omega \subset \mathbb{T}$ . Then there exist meromorphic functions  $f_{e_1}: \Omega_1 \rightarrow C(i_1)$  and  $f_{e_2}: \Omega_2 \rightarrow C(i_1)$  with  $\Omega_1 = P_1(\Omega)$  and  $\Omega_2 = P_2(\Omega)$ , such that  $f(z_1 + z_2 i_2) = f_{e_1}(z_1 - z_2 i_1)e_1 + f_{e_2}(z_1 + z_2 i_1)e_2 \forall z_1 + z_2 i_2 \in \Omega$

Based on the above definition of bicomplex meromorphic function, we extend algebraic properties to bicomplex meromorphic functions as follows:

**Theorem 2.3.3:** If  $f^1, f^2: \Omega \rightarrow \mathbb{T}$  be two bicomplex meromorphic functions on the open set  $\Omega$ . Then  $f^1 + f^2: \Omega \rightarrow \mathbb{T}$  be a bicomplex meromorphic function on the open set  $\Omega$ .

**Proof :** Since  $f^1$  and  $f^2$  are bicomplex meromorphic functions. Therefore, by definition of bicomplex meromorphic  $f^1$  and  $f^2$  can be written as

$$f^1(z_1 + z_2 i_2) = f_{e_1}^1(z_1 - z_2 i_1)e_1 + f_{e_2}^1(z_1 + z_2 i_1)e_2 \forall z_1 + z_2 i_2 \in \Omega \dots \dots (1)$$

$$f^2(z_1 + z_2 i_2) = f_{e_1}^2(z_1 - z_2 i_1)e_1 + f_{e_2}^2(z_1 + z_2 i_1)e_2 \forall z_1 + z_2 i_2 \in \Omega \dots \dots (2)$$

Now, let's define the sum of these two bicomplex meromorphic functions as

$$f_{e_2}(z_1 - z_2 i_1)e_2$$

$$f(z_1 + z_2 i_2) = f^1(z_1 + z_2 i_2) + f^2(z_1 + z_2 i_2)$$

$$\begin{aligned} &= f_{e_1}^1(z_1 - z_2 i_1)e_1 + f_{e_2}^1(z_1 + z_2 i_1)e_2 + f_{e_1}^2(z_1 - z_2 i_1)e_1 + f_{e_2}^2(z_1 + z_2 i_1)e_2 \\ &= [f_{e_1}^1(z_1 - z_2 i_1) + f_{e_1}^2(z_1 - z_2 i_1)]e_1 + [f_{e_2}^1(z_1 + z_2 i_1) + f_{e_2}^2(z_1 + z_2 i_1)]e_2 \\ &= f_{e_2}(z_1 - z_2 i_1)e_2 \text{ [because the sum of two meromorphic functions is a meromorphic function]} \end{aligned}$$

Therefore,  $f(z_1 + z_2 i_2) = f_{e_2}(z_1 - z_2 i_1)e_2$  is a bicomplex meromorphic function, where  $f_{e_i}$  is meromorphic in  $\Omega_i$  for  $i = 1, 2$ .

**Theorem 2.3.4:** If  $f^1, f^2: \Omega \rightarrow \mathbb{T}$  be two bicomplex meromorphic functions on the open set  $\Omega$ . Then  $f^1 \cdot f^2: \Omega \rightarrow \mathbb{T}$  be a bicomplex meromorphic function on the open set  $\Omega$ .

**Proof.** Since  $f^1$  and  $f^2$  are bicomplex meromorphic functions on the open set  $\Omega$ . Therefore, by Theorem 2.2.2, there exist meromorphic functions  $f_{e_1}: \Omega_1 \rightarrow C(i_1)$  and  $f_{e_2}: \Omega_2 \rightarrow C(i_1)$  with  $\Omega_1 = P_1(\Omega)$  and  $\Omega_2 = P_2(\Omega)$ , such that

$$\begin{aligned} f(z_1 + z_2 i_2) &= f_{e_1}(z_1 - z_2 i_1)e_1 + f_{e_2}(z_1 + z_2 i_1)e_2 \forall z_1 + z_2 i_2 \in \Omega \\ f^1(z_1 + z_2 i_2) &= f_{e_1}^1(z_1 - z_2 i_1)e_1 + f_{e_2}^1(z_1 + z_2 i_1)e_2 \forall z_1 + z_2 i_2 \in \Omega \\ f^2(z_1 + z_2 i_2) &= f_{e_1}^2(z_1 - z_2 i_1)e_1 + f_{e_2}^2(z_1 + z_2 i_1)e_2 \forall z_1 + z_2 i_2 \in \Omega \end{aligned}$$

To show that the product of two bicomplex meromorphic functions is a bicomplex meromorphic. Let's define the product of these two bicomplex meromorphic functions as

$$f(z_1 + z_2 i_2) = f^1(z_1 + z_2 i_2) \cdot f^2(z_1 + z_2 i_2)$$

From (1) and (2), we have

$$\begin{aligned} f(z_1 + z_2 i_2) &= f_{e_2}^2(z_1 + z_2 i_1)e_2 \\ &= [(f_{e_2}^1(z_1 + z_2 i_1)) \cdot (f_{e_2}^2(z_1 + z_2 i_1))]e_2 \\ &= [(f_{e_2}^1(z_1 + z_2 i_1)) \cdot (f_{e_2}^2(z_1 + z_2 i_1))]e_2 \\ &= f_{e_2}(z_1 + z_2 i_1)e_2 \text{ [product of two meromorphic functions is a meromorphic function]} \end{aligned}$$

where  $f_{e_i}$  is meromorphic in  $\Omega_i$  for  $i = 1, 2$ .

**Theorem 2.3.5 :** If  $f: \Omega \subseteq \mathbb{T} \rightarrow \mathbb{T}$  be a bicomplex meromorphic function on the open set  $\Omega$  and  $c$  be any complex number. Then  $c \cdot f$  is also a bicomplex meromorphic function.

**Proof.** Since  $f: \Omega \subseteq \mathbb{T} \rightarrow \mathbb{T}$  be a bicomplex meromorphic function on the open set  $\Omega$ . Then  $f$  is a quotient  $\frac{g(w)}{h(w)}$  of two bicomplex holomorphic functions, we need to show that  $c \cdot f(w)$  can be expressed in this form as well. For this, assume that  $f(w) = \frac{g(w)}{h(w)}$  where  $g(w)$  and  $h(w)$  are bicomplex holomorphic functions in  $\Omega$  and  $h(w)$  is not identically zero in any component of  $\Omega$  where  $z_1 + z_2 i_2 \in \Omega$ . Therefore, from Theorem 2.1.2, there exist holomorphic functions  $f_{e_1}: \Omega_1 \rightarrow C(i_1)$  and  $f_{e_2}: \Omega_2 \rightarrow C(i_1)$  with  $\Omega_1 = P_1(\Omega)$  and  $\Omega_2 = P_2(\Omega)$ , such that  $f(z_1 + z_2 i_2) = f_{e_1}(z_1 - z_2 i_1)e_1 + f_{e_2}(z_1 + z_2 i_1)e_2 \forall z_1 + z_2 i_2 \in \Omega$

To show that  $c \cdot f(w)$  it is a bicomplex meromorphic function, define a new functions  $G(w) = c \cdot g(w)$  and  $H(w) = h(w)$ . Then  $G(w)$  and  $H(w)$  are bicomplex holomorphic functions. Therefore,  $G(w)$  and  $H(w)$  can be written as

$$G(w) \quad G(z_1 + z_2 i_2) = G_{e_1}(z_1 - z_2 i_1)e_1 + G_{e_2}(z_1 + z_2 i_1)e_2 \quad (3)$$

$$H(w) \quad H(z_1 + z_2 i_2) = H_{e_1}(z_1 - z_2 i_1)e_1 + H_{e_2}(z_1 + z_2 i_1)e_2 \quad (4)$$

From (1) and (2), we have

$$\begin{aligned} f(w) &= \frac{G(w)}{H(w)} = \frac{G_{e_1}(z_1 - z_2 i_1)e_1 + G_{e_2}(z_1 + z_2 i_1)e_2}{H_{e_1}(z_1 - z_2 i_1)e_1 + H_{e_2}(z_1 + z_2 i_1)e_2} \\ &= \frac{G_{e_1}(z_1 - z_2 i_1)}{H_{e_1}(z_1 - z_2 i_1)} e_1 + \frac{G_{e_2}(z_1 + z_2 i_1)}{H_{e_2}(z_1 + z_2 i_1)} e_2 \\ &= F_{e_1}(z_1 - z_2 i_1)e_1 + F_{e_2}(z_1 + z_2 i_1)e_2 \end{aligned}$$

where  $F_{e_i}$  is meromorphic in  $\Omega_i$  for  $i = 1, 2$ .

Hence, scalar multiplication of bicomplex meromorphic function is bicomplex meromorphic.

### 3. Bicomplex $Q_m$ - Normal Families

In [4]  $Q_m$ - Normal families of one complex variable of finite order is developed in detail. We intend to develop the theory for bicomplex variables. The theory of bicomplex functions is currently a topic of interest, as it is closely related to Clifford algebras and multicomplex analysis, making it a significant area of study in recent research. In [6], Riley first talked about the bicomplex functions. Later, we find a monograph by G.B. Price [1], and recently, a monography [16] has been written by Leuna et al. In [8], K.S. Charak and N. sharma have defined bicomplex normal families. For developing bicomplex normal families, they have constructed the bicomplex extended plane  $\hat{C}$ . In this paper, we shall define Bicomplex  $Q_m$ -Normal families and investigate its properties.

**Definition 3.1:** Let  $S = \{f_n\}$  be a sequence of bicomplex meromorphic functions defined in a domain  $\Omega$ . A point  $Z_0$  of  $\Omega$  is called a  $C_0$ -point of  $S$  if there exists a disc  $D(Z_0, r_1, r_2) = \{\|Z - Z_0\| < r, r = \min(r_1, r_2)\} \subseteq \Omega$  such that the sequence  $S$  is uniformly spherically convergent in  $D(Z_0, r_1, r_2)$ .  $S$  is said to be a  $C_0$ -sequence in  $\Omega$  if  $\forall Z_0 \in \Omega, S$  is a  $C_0$ -sequence.

To understand the definition, let us consider the sequence of bicomplex meromorphic functions  $S = \{f_n(Z)\}$  defined in the domain  $\Omega \subseteq \mathbb{T}$  where each  $f_n(Z)$  is given by:

$$f_n(Z) = \frac{1}{Z_1 - n} + \frac{1}{Z_2 - n}, n \in N$$

Then for each  $n \in N, f_n(Z)$  has singularities at  $Z_1 = n$  and  $Z_2 = n$ . However, as  $n \rightarrow \infty$ , the singularities move towards infinity, and  $f_n(Z)$  becomes meromorphic in  $\Omega$  for large enough  $n$ . Therefore, as  $n \rightarrow \infty$ , the sequence  $S$  converges uniformly on compact subsets of  $\Omega$ . Since  $S$  converges uniformly on compact subsets of  $\Omega$  as  $n \rightarrow \infty$ , every point  $Z_0 \in \Omega$  can be considered a  $C_0$ -point of  $S$ . Hence,  $S$  is a  $C_0$ -sequence in  $\Omega$ . This example illustrates the concept of a  $C_0$ -point and a  $C_0$ -sequence for a sequence of bicomplex meromorphic functions in the domain  $\Omega \subseteq \mathbb{T}$ .

**Definition 3.2:** Let  $S = \{f_n\}$  be a sequence of bicomplex meromorphic functions in a domain  $\Omega$ . A point  $Z_0$  of  $\Omega$  is called a  $C_1$ -point of  $S$  if  $\exists$  a disc  $D(Z_0, r_1, r_2) = \{\|Z - Z_0\| < r, r = \min(r_1, r_2)\} \subseteq \Omega$  such that each point of  $D_0(Z_0, r_1, r_2) = \{0 < \|Z - Z_0\| < r\}$  is a  $C_0$ -point of  $S$ .  $S$  is called a  $C_1$ -Sequence in  $\Omega$  if each point of  $\Omega$  is a  $C_1$ -point of  $S$ . Suppose we denote by  $E$  the set of all non  $C_0$ -points of  $S$  in  $\Omega$ . Then  $E = \phi$  if  $S$  is a  $C_0$ -sequence and  $E_\Omega^1 = \phi$  if  $S$  is a  $C_1$ -Sequence. By generalizing this, we see that it is natural to have  $E_\Omega^2 = \phi, E_\Omega^3 = \phi$  enhancing it we define.

**Definition 3.3:** Let  $S = \{f_n\}$  be a sequence of bicomplex meromorphic functions in a domain  $\Omega$  and  $Z_0$  a point of  $\Omega$ . We say that  $Z_0$  is a  $C_m$ -point of  $S$ ,  $m \geq 2$  if there is a discus  $D(Z_0, r_1, r_2) = \{\|Z - Z_0\| < r, r = \min(r_1, r_2)\} \subseteq \Omega$  such that each point of  $D_0(Z_0, r_1, r_2) = \{0 < \|Z - Z_0\| < r\}$  is a  $C_{m-1}$ -point of  $S$ . In this way,  $C_m$ -point of  $S$  can be defined for each integer  $m \geq 0$ .

Example of  $C_m$ -point Let  $S = \{f_n(Z)\}$  be the sequence of bicomplex meromorphic functions defined in the domain  $\Omega = \{Z \in T: |Z_1| < 1, |Z_2| < 1\}$  where each  $f_n(Z)$  is given by:

$$f_n(Z) = \frac{1}{Z_1 - n} + \frac{1}{Z_2 - n}, n \in N$$

Now, let's take a point  $Z_0 = (1,1) \in \Omega$ . We want to show that  $Z_0$  is a  $C_m$ -point of  $S$  for  $Z$ . Let  $D(Z_0, r_1, r_2)$  be a bicomplex disc centered at  $Z_0$  with radii  $r_1 = r_2 = 1/2$ , i.e.  $D(Z_0, 1/2, 1/2) = \{Z \in T: \|Z - Z_0\| < 1/2\}$ . We need to check that each point in the annulus  $D_0(Z_0, r_1, r_2) = \{Z \in T: 0 < \|Z - Z_0\| < 1/2\}$  is a  $C_{m-1}$ -point  $S$ . For any  $Z \in D_0(Z_0, r_1, r_2)$ , let's compute  $f_n(Z)$  for some  $n$ . For simplicity, let's take  $n = 2$ .

$$f_2(Z) = \frac{1}{Z_1-2} + \frac{1}{Z_2-2}$$

Since  $Z$  lies in  $D_0(Z_0, r_1, r_2)$  both  $|Z_1-2|$  and  $|Z_2-2|$  are greater than  $1/2$ , ensuring that  $f_2(Z)$  is well-defined and meromorphic in  $D_0(Z_0, r_1, r_2)$ . Thus,  $Z_0$  is a  $C_1$ -point of  $S$ . Since  $Z_0$  is a  $C_1$ -point of  $S$ , by induction, it can be shown that  $Z_0$  is a  $C_m$ -point of for all  $m \geq 2$ . This example illustrates the concept of a  $C_m$ -point of a sequence of bicomplex meromorphic functions, where the function behaves well in a neighborhood of the point, even if the point itself is singular.

**Definition 3.4:** A sequence  $S$  is said to be  $C_m$ -Sequence in  $\Omega$  if each point of  $\Omega$  is a  $C_m$ -point of  $S$ .

**Theorem 3.5 :** Every  $C_m$ -sequence of bicomplex meromorphic function defined in a domain  $\Omega$  is  $C_{m-1}$ -sequence in  $\Omega$ . But converse is not true.

**Proof:**  $C_m$ -sequence implies  $C_{m-1}$ -sequence: Let  $S$  be a  $C_m$ -sequence in  $\Omega$ . Then by definition, for every point  $Z_0 \in \Omega$ , there exists a discus  $D(Z_0, r_1, r_2)$  such that each point in  $D(Z_0, r_1, r_2)$  is a  $C_{m-1}$ -point of  $S$ . Therefore,  $S$  behaves well enough in a neighborhood of each point to have no singularities up to order  $m - 1$ . Hence,  $S$  is also a  $C_{m-1}$ -sequence in  $\Omega$ .

The converse of the theorem is not true. To prove that the converse is not necessarily true, let's consider a specific example:

Let  $S = \{f_n(Z)\}$  be the sequence of bicomplex meromorphic functions defined in the domain  $\Omega \subseteq C^2$ , where each  $f_n(Z)$  is given by:

$$f_n(Z) = \frac{1}{(Z_1 - n)^2} + \frac{1}{(Z_2 - n)^2}, n \in N$$

Then each  $f_n(Z)$  has singularities at  $Z_1 = n$  and  $Z_2 = n$ . As  $n$  increases, the singularities become stronger (second-order poles). Therefore, for each  $n$ , there exists a discus  $D_0(Z_0, r_1, r_2)$  centered at  $(n, n)$  such that  $S$  behaves well enough to be a  $C_1$ -sequence. To prove that the sequence  $S = \{f_n(Z)\}$  does not become a  $C_2$ -sequence  $n \rightarrow \infty$ , we need to show that there exist points in  $\Omega$  where the functions in  $S$  do not behave well enough to have no singularities up to order 2. For a sequence to be a  $C_2$ -sequence, every point in  $\Omega$  must be a  $C_2$ -point of  $S$ . This means that there must exist a disc centered at each point  $Z_0 \in \Omega$  such that every point in the annulus  $D_0(Z_0, r_1, r_2)$  is a  $C_1$ -point of  $S$ . Now, consider the behavior of  $S$  as  $n \rightarrow \infty$ . The functions  $f_n(Z)$  have singularities at  $Z_1 = n$  and  $Z_2 = n$ , and as  $n$  increases, the singularities become stronger (second-order poles). However  $n \rightarrow \infty$ , the distance between the singularities and any fixed point in  $\Omega$  also tends to infinity. This means that for any fixed point  $Z_0 \in \Omega$ , no matter how large  $n$  becomes, there will always be a neighborhood around  $Z_0$  that contains the singularities of  $f_n(Z)$ . Therefore, there does not exist a disc centered at  $Z_0$  such that every point in the annulus  $D_0(Z_0, r_1, r_2)$  is a  $C_1$ -point of  $S$ . Consequently,  $S$  does not become a  $C_2$ -sequence as  $n \rightarrow \infty$ . Generalizing in this way, we conclude that every  $C_m$ -sequence in a domain  $\Omega$  is  $C_{m-1}$ -sequence, but the converse is not true.

The converse of the theorem is not true. To prove that the converse is not necessarily true, let's consider a specific example:

Let  $S = \{f_n(Z)\}$  be the sequence of bicomplex meromorphic functions defined in the domain  $\Omega \subseteq C^2$ , where each  $f_n(Z)$  is given by:

$$f_n(Z) = \frac{1}{(Z_1 - n)^2} + \frac{1}{(Z_2 - n)^2}, n \in N$$

Then, each  $f_n(Z)$  has singularities at  $Z_1 = n$  and  $Z_2 = n$ . As  $n$  increases, the singularities become stronger (second-order poles). Therefore, for each  $n$ , there exists a disc  $D_0(Z_0, r_1, r_2)$  centered at  $(n, n)$  such that  $S$  behaves well enough to be a  $C_1$ -sequence. To prove that the sequence  $S = \{f_n(Z)\}$  does not become a  $C_2$ -sequence  $n \rightarrow \infty$ , we need to show that there exist points in  $\Omega$  where the functions  $S$  do not behave well enough to have no singularities up to order 2. For a sequence to be a  $C_2$ -sequence, every point in  $\Omega$  must be a  $C_2$ -point of  $S$ . This means that there must exist a disc centered at each point  $Z_0 \in \Omega$  such that every point in the annulus  $D_0(Z_0, r_1, r_2)$  is a  $C_1$ -point of  $S$ . Now, consider the behavior of  $S$  as  $n \rightarrow \infty$ . The functions  $f_n(Z)$  have singularities at  $Z_1 = n$  and  $Z_2 = n$ , and as  $n$  increases, the singularities become stronger (second-order poles). However  $n \rightarrow \infty$ , the distance between the singularities and any fixed point in  $\Omega$  also tends to infinity. This means that for any fixed point  $Z_0 \in \Omega$ , no matter how large  $n$  becomes, there will always be a neighborhood around  $Z_0$  that contains the singularities of  $f_n(Z)$ . Therefore, there does not exist a disc centered at  $Z_0$  such that every point in the annulus  $D_0(Z_0, r_1, r_2)$  is a  $C_1$ -point of  $S$ . Consequently,  $S$  does not become a  $C_2$ -sequence as  $n \rightarrow \infty$ . Generalizing in this way, we conclude that every  $C_m$ -sequence in a domain  $\Omega$  is  $C_{m-1}$ -sequence, but the converse is not true.

**Lemma 3.6:** If for some integers  $m \geq 2$ ,  $Z_0$  is a  $C_m$ -point of  $S$ , then

- (I)  $Z_0$  is a  $C_{m+1}$ -point of  $S$
- (II) there exists a disc  $D(Z_0, r_1, r_2) = \{||Z - Z_0|| < r, r = \min(r_1, r_2)\} \subseteq \Omega$  such that each point of which is a  $C_m$ -point of  $S$ .
- (III)  $Z_0$  is a  $C_m$ -point of every subsequence of  $S$ .

**Proof.** Assume that  $Z_0$  is a  $C_m$ -point of  $S$ . Then, by definition of  $C_m$ -point, there exists a disc  $D(Z_0, r_1, r_2) = \{||Z - Z_0|| < r, r = \min(r_1, r_2)\} \subseteq \Omega$  such that each point of  $D_0(Z_0, r_1, r_2) = \{0 < ||Z - Z_0|| < r\}$  is a  $C_1$ -point of  $S$ . We have to prove that  $Z_0$  is a  $C_3$ -point of  $S$ . Since  $Z_0$  is a  $C_2$ -point of  $S$ , there exists a disk  $\Delta = \{||Z - Z_0|| < r\} \subseteq \Omega$  such that each point of  $\Delta_0 = \{0 < ||Z - Z_0|| < r\}$  is a  $C_1$ -point of  $S$ . Now, each  $C_1$ -point is a  $C_0$ -point by definition.

Assume that the result is true for  $m = k$ , that is, if  $Z_0$  is a  $C_k$ -point of  $S$ , then  $Z_0$  is a  $C_{k+1}$ -point of  $S$ , there exists a disk such that each point is a  $C_k$ -point of  $S$  and hence  $Z_0$  is a  $C_k$ -point of every sub-sequence. Now, we have to prove the result for  $m = k + 1$ . For this, we have to prove that  $Z_0$  is a  $C_{k+2}$ -point. By the assumption,  $Z_0$  is a  $C_{k+1}$ -point. Therefore, there exists a disc

$D(Z_0, r_1, r_2) = \{||Z - Z_0|| < r, r = \min(r_1, r_2)\} \subseteq \Omega$  such that each point of  $D_0(Z_0, r_1, r_2) = \{0 < ||Z - Z_0|| < r\}$  is a  $C_k$ -point of  $S$ . Now, by the inductive hypothesis, each  $C_k$ -point is a  $C_{k+1}$ -point. Therefore,  $Z_0$  is a  $C_{k+2}$ -point

**Proof of II** Assume that  $Z_0$  is a  $C_m$ -point of  $S$ . Then, by definition of  $C_m$ -point, there exists a disc  $D(Z_0, r_1, r_2) = \{||Z - Z_0|| < r, r = \min(r_1, r_2)\} \subseteq \Omega$  such that each point of  $D_0(Z_0, r_1, r_2) = \{0 < ||Z - Z_0|| < r\}$  is a  $C_{m-1}$ -point of  $S$ . Now we want to show that each point of  $D_0$  is also a  $C_m$ -point of  $S$ . For the sake of simplicity, let's take this disk as  $D_1$ . Let  $Z'$  be a  $C_{m-1}$ -point of  $D_1$ . Since  $D_1$  is a subset of  $D$ . Therefore,  $Z'$  is also a point of  $D$ , and thus,  $Z'$  is a  $C_{m-1}$ -point of  $S$ .

Since the above reasoning holds for any  $Z'$  in  $D_1$ , and  $D_1$  is a subset of  $D$ , it is concluded that every point in  $D$  is a  $C_{m-1}$ -point of  $S$ . Since each point of  $D$  is already a  $C_{m-1}$ -point of  $S$ , we can use the same disk  $D$  to show that every point in  $D$  is also a  $C_m$ -point of  $S$ . Thus we have shown that if  $Z_0$  is a  $C_m$ -point of  $S$ , then there exists a disc  $\{||Z - Z_0|| < r\}$  such that every point of this disc is also a  $C_m$ -point of  $S$ .

**Proof (III)** Assume that  $Z_0$  is a  $C_m$ -point of  $S$ . Then by definition of  $C_m$ -point, there exists a disc  $D_0(Z_0, r_1, r_2) = \{||Z - Z_0|| < r, r = \min(r_1, r_2)\} \subseteq \Omega$  such that each point of  $D(Z_0, r_1, r_2) = \{0 < ||Z - Z_0|| < r\}$  is a  $C_{m-1}$ -point of  $S$ . Now, consider any subsequence  $S'$  of  $S$ . We want to prove that  $Z_0$  is a  $C_m$ -point of  $S'$ . Since  $Z_0$  is a  $C_m$ -point of  $S$ . Therefore, there exists a disc such that every point of which is a  $C_{m-1}$ -point of  $S$ . Thus the same disc works for the subsequence  $S'$  as well. Clearly  $Z_0$  is a  $C_{m-1}$ -point of  $S'$ . Now,  $Z_0$  is a  $C_{m-1}$ -point of  $S'$ , by the definition of  $C_m$ -point,  $Z_0$  is also a  $C_m$ -point of  $S'$ . Since  $S'$  is an arbitrary subsequence of  $S$ . Therefore, it holds for all subsequences of  $S$ . Thus we have proved that if  $Z_0$  is a  $C_m$ -point of  $S$ , then  $Z_0$  is a  $C_m$ -point of every subsequence of  $S$ .

**Lemma 3.7:** For some integers  $m \geq 2$ , if  $S$  is a  $C_m$ -sequence in  $\Omega$ . Then  $S$  is  $C_{m+1}$  sequence in  $\Omega$  and every subsequence of  $S$  is a  $C_m$ -sequence in  $\Omega$ .

Proof: Suppose  $S$  is a  $C_m$ -sequence in  $\Omega$ . This means that for every  $C_m$ -point  $Z_0$  of  $S$ , there exists a disc  $D(Z_0, r_1, r_2) \subseteq \Omega$  such that each point of  $D(Z_0, r_1, r_2) = \{0 < ||Z - Z_0|| < r\}$  is a  $C_{m-1}$ -point of  $S$ . Now, let's show that  $S$  is a  $C_{m+1}$ -sequence in  $\Omega$ . Let  $Z_0$  be a  $C_m$ -point of  $S$ , and let  $D(Z_0, r_1, r_2)$  be the corresponding disc as per the definition. Since each point of  $D_0(Z_0, r_1, r_2)$  is a  $C_{m-1}$ -point of  $S$ , by the induction hypothesis,  $S$  is a  $C_m$ -sequence in  $D_0(Z_0, r_1, r_2)$ . Now, consider the compact subset  $D'(Z_0, r_1, r_2) = D(Z_0, r_1, r_2) \cup D_0(Z_0, r_1, r_2)$  of  $\Omega$ . By the continuity of  $S$ ,  $S$  is bounded on  $D'(Z_0, r_1, r_2)$ . Now, let's consider an arbitrary compact subset  $K$  of  $\Omega$ . Since  $K$  is compact, there exists a finite number of  $C_m$ -points of  $S$  contained in  $K$ . Let  $Z_1, Z_2, \dots, Z_n$  be these  $C_m$ -points. For each  $Z_i$ , we can find a corresponding disc  $D(Z_i, r_{1i}, r_{2i})$  such that  $S$  is a  $C_m$ -sequence in  $D(Z_i, r_{1i}, r_{2i})$ . Now, consider the union of all these discs and  $K$ :  $D' = \bigcup_{i=1}^n D(Z_i, r_{1i}, r_{2i}) \cup K$ . This is a compact subset of  $\Omega$ . Since  $S$  is bounded on  $D'$  and  $K \subseteq D'$ ,  $S$  is bounded on  $K$ . Hence,  $S$  is a  $C_{m+1}$ -sequence in  $\Omega$ .

Now, to prove that every subsequence of  $S$  is a  $C_m$ -sequence in  $\Omega$ . Let  $S'$  be a subsequence of  $S$ . Since  $S'$  is a subset of  $S$ , it inherits the property of being a  $C_m$ -sequence in  $\Omega$ .

Thus we have shown that if  $S$  is a  $C_m$ -sequence in  $\Omega$ , then  $S$  is a  $C_{m+1}$ -sequence in  $\Omega$ , and every subsequence of  $S$  is also a  $C_m$ -sequence in  $\Omega$ .

**Definition 3.8:** A point  $Z_0 \in \Omega$  is said to be non- $C_m$ -point of  $S$  if  $Z_0$  is not  $C_m$ -point of  $S$ . The set of all non- $C_m$ -points is denoted by  $E$ .

$W_m$ - property: If  $E_\Omega^j, j=0,1, \dots, m \neq \phi$ , we say that the set  $E$  has  $W_m$ - property w.r.t  $\Omega$ .

**Theorem 3.9:** Let  $S = \{f_n(Z)\}$  be a sequence of bicomplex meromorphic functions in a domain  $\Omega$ . Let  $Z_0 \in \Omega$ . Then  $Z_0$  is a non  $C_m$ -point of  $S$  if and only if  $Z_0 \in E_\Omega^m$ , where  $E$  is the set of non

$C_0$ -points of  $S$  in  $\Omega$ .

**Proof :** Let  $E$  denote the set of non- $C_0$ -points of  $S$  in  $\Omega$ . Then,  $E$  contains all points where the functions in  $S$  have singularities.

To prove the theorem, we shall establish the equivalence between a point  $Z_0$  being a non- $C_m$ -point of  $S$  and  $Z_0$  belonging to  $E_\Omega^m$ , where  $E$  is the set of non- $C_0$ -points of  $S$  in  $\Omega$ .

For this, first assume that  $Z_0$  is a non- $C_m$ -point of  $S$ . This means that there does not exist a disc  $D(Z_0, r_1, r_2)$  such that every point in  $D_0(Z_0, r_1, r_2)$  is a  $C_{m-1}$ -point of  $S$ . Since  $Z_0$  is not a  $C_m$ -point, it implies that  $E_\Omega^m \neq \phi$ , because there exists at least one point, namely  $Z_0$ , in  $E_\Omega^m$ .

Conversely assume that  $Z_0 \in E_\Omega^m$ . we shall prove that  $Z_0$  is a non- $C_m$ -point of  $S$ . Since  $Z_0 \in E_\Omega^m$ . This means that there exists a disc  $D_0(Z_0, r_1, r_2)$  such that every point in  $D_0(Z_0, r_1, r_2)$  is a non- $C_{m-1}$ -point of  $S$ . If  $Z_0$  is a  $C_m$ -point, then every point in  $D_0(Z_0, r_1, r_2)$  would be a  $C_{m-1}$ -point by definition. Since this is not the case,  $Z_0$  cannot be a  $C_m$ -point. Therefore,  $Z_0$  is a non- $C_m$ -point of  $S$ . Which completes the proof of the theorem.

**Definition 3.10 :** Let  $F$  be a family of bicomplex meromorphic functions in a domain  $\Omega$  and  $m \geq 0 \in \mathbb{Z}$ , we say that  $F$  is  $Q_m$ - Normal family in  $\Omega$  if from every sequence of functions of the family  $F$ , we can extract a subsequence which is  $C_m$ -sequence in  $\Omega$ . That is  $F$  is  $Q_m$ - Normal at point  $Z_0 \in \Omega$  if there exists a disc  $D(Z_0, r_1, r_2) \subseteq \Omega$  such that  $F$  is  $Q_m$ - Normal in  $D(Z_0, r_1, r_2)$ . In particular,  $Q_0$ - Normal family is normal family and  $Q_1$ - Normal family is quasi-normal family in  $\Omega$ .

**Theorem 3.11:** Let  $F$  be a family of bicomplex meromorphic functions in a domain  $\Omega$  and  $m \geq 0 \in \mathbb{Z}$  if  $F$  is  $Q_m$ - Normal at each point of  $\Omega$ , then  $F$  is  $Q_m$ - Normal in  $\Omega$ .

**Proof:** First of all, we consider a sequence  $\{Z_j\}, j=1,2,3,\dots$  in  $\Omega$  such that each point of  $\Omega$  is a limiting point of the sequence  $\{Z_j\}$ . Now by hypothesis a disc  $D(Z_j, r_{1j}, r_{2j}) \subseteq \Omega$  such that  $F$  is  $Q_m$ -normal in  $D(Z_j, r_{1j}, r_{2j})$ . Let  $R_j$  be the least upper bound of the set of members  $\{r_{1j}, r_{2j}\}$  having this property. Define disc  $D_j = D(Z_j, R_j/2, R_j/2)$  for each  $Z_j$ . If  $R_j = \infty$ , then  $D_j$  covers  $\Omega$ , otherwise,  $D_j$  is contained in  $\Omega$  and the family is  $Q_m$ . Normal in  $D_j$ . Now let  $S_1 = \{f_n(z)\}, n=1,2,\dots$  be sequence of functions of the family  $F$  from  $S$  be just a subsequence  $S_1 = \{f_{\alpha_1}(z), f_{\alpha_2}(z), \dots\}$ , which is a  $C_m$ -sequence in  $D_1$ . From  $S_1$  we can get a sequence  $S_g : \{f_{\beta_1}(z), f_{\beta_2}(z), \dots\}$ , which is a  $C_m$ -sequence in  $D_2$ . In this way we get successively a sequence  $S_p, p = 1,2,3, \dots$  such that for each  $p \geq 1, S_p$  is a  $C_m$ -sequence in  $D_p$  and  $S_{p+1}$  is a subsequence of  $S_p$ . Consider the diagonal sequence

$S' = f_{\alpha_1}(z), f_{\beta_2}(z), f_{\gamma_3}(z), \dots, f_{\lambda_k}(z), \dots$ . Now  $S'$  is a subsequence of  $\{f_{n_k}(z)\}, (k=1,2,3,\dots)$  of  $S$  since for each  $k$  the terms  $f_{n_k}(z), f_{n_{k+1}}(z), \dots$  all belongs the sequence  $\{S_k\}$ . Hence  $S'$  is a  $C_m$ -sequence in each of the  $D_j, j=1,2,3,\dots$

Consider the point  $Z'$  of  $\Omega$ . Since each  $D_j$  covers  $\Omega$ , there exists a disc  $D(Z', \rho_1, \rho_2)$  contained in some  $D_j$ . By construction,  $F$  is  $Q_m$ -normal in  $D(Z', \rho_1, \rho_2)$ . If  $R_j < \infty$ , then  $\rho_1 < R_j/2$  and  $\rho_2 < R_j/2$  for some  $j$ . Hence,  $F$  is  $Q_m$ -normal in  $D(Z', 2\rho_1, 2\rho_2) \subset D_j$ . If  $R_j < \infty$ , then since  $\rho_1, \rho_2 < 1$ ,  $D(Z', \rho_1, \rho_2)$  is contained in  $D_j$ . Thus,  $F$  is  $Q_m$ -normal in  $D(Z', \rho_1, \rho_2)$ . Since  $Z'$  is arbitrary,  $S'$  is a  $C_m$ -sequence in  $\Omega$ . Hence,  $F$  is  $Q_m$ -normal in  $\Omega$

Which completes the proof of the theorem.

**Lemma 3.12 :** For an integer  $m \geq 0$ , If the family  $F$  of bicomplex meromorphic functions defined in a domain  $\Omega$  is  $Q_m$ -Normal in  $\Omega$ , then  $F$  is  $Q_{m+1}$ -Normal in  $\Omega$ .

**Proof:** We shall prove this result by the Principle of Mathematical Induction. First, we prove the base case when  $m = 0$ . Suppose  $F$  is  $Q_0$ -normal in  $\Omega$ . By definition, this means that for every compact subset  $K$  of  $\Omega$ , there exists a constant  $M_K$  such that for every  $f \in F$ , we have  $|f(z)| \leq M_K$  for all  $Z \in K$ . Now, let  $K$  be a compact subset of  $\Omega$ . Since  $F$  is  $Q_0$ -normal, there exists  $M_K$  such that  $|||f(Z)||| \leq M_K$  for all  $f \in F$  and  $Z \in K$ . Now, consider the set  $Q_1(K) = \{Z \in \Omega : |||Z||| \leq M_K\}$ . This set is compact since it is closed and bounded. Therefore,  $F$  is  $Q_1$ -normal in  $\Omega$ . Now, assume that for some integer  $m \geq 0$ , if  $F$  is  $Q_m$ -normal in  $\Omega$ , then  $F$  is  $Q_{m+1}$ -normal in  $\Omega$ . Now, let's prove that if  $F$  is  $Q_{m+1}$ -normal in  $\Omega$ , then  $F$  is  $Q_{m+2}$ -normal in  $\Omega$ . Suppose  $F$  is  $Q_{m+1}$ -normal in  $\Omega$ . By definition, this means that for every compact subset  $K$  of  $\Omega$ , there exists a constant  $M_K$  such that for every  $f \in F$ , we have  $|||f(Z)||| \leq M_K(1 + |Z|)^{m+1}$  for all  $Z \in K$ . Now, let  $K$  be a compact subset of  $\Omega$ . Since  $F$  is  $Q_{m+1}$ -normal, there exists  $M_K$  such that  $|||f(Z)||| \leq M_K(1 + |Z|)^{m+1}$  for all  $f \in F$  and  $Z \in K$ . Now, consider the set  $Q_{m+2}(K) = \{Z \in \Omega : |z| \leq M_K\}$ . This set is compact since it is closed and bounded. Therefore,  $F$  is  $Q_{m+2}$ -normal in  $\Omega$ .

By induction, the result follows for all non-negative integers  $m$ . Therefore, if  $F$  is  $Q_m$ -normal in  $\Omega$ , then  $F$  is  $Q_{m+1}$ -normal in  $\Omega$ .

**Theorem 3.13 :** A family  $F$  of bicomplex meromorphic functions defined on a domain  $\Omega \subseteq T$  is  $Q_m$ -normal with respect to the bicomplex chordal metric if and only if the family of meromorphic functions on  $F_{e_i} = P_i(F)$  is  $Q_m$ -normal in  $P_i(\Omega)$  for  $i=1,2$  with respect to the chordal metric.

**Proof:** Assume that  $F$  is  $Q_m$ -normal with respect to the bicomplex chordal metric on  $\Omega$ . We want to show that  $F_{e_i} = P_i(F)$  is  $Q_m$ -normal in  $P_i(\Omega)$  for  $i=1,2$ . For this, let  $\{(f_n)_1\}$  be a sequence in  $F_{e_1} = P_1(F)$ . We want to show, without loss of generality that from the sequence of meromorphic functions  $\{(f_n)_1\}$ , we can extract a subsequence which is  $C_m$ -sequence in  $P_1(\Omega)$ .

[Since  $F$  is normal in  $\Omega$ , we can find a sequence  $\{f_n\}$  in  $F$  such that  $\{P_1(f_n)\} = \{(f_n)_1\}$ . Moreover for any  $z_0 \in P_1(\Omega)$ , we can find a  $w_0 \in \Omega$  such that  $P_1(w_0) = z_0$ . Now consider a closed disc  $\bar{D}(w_0, r, r)$  in  $\Omega$ . By hypothesis, the sequence  $\{f_n\}$  contains a subsequence  $\{f_{n_k}\}$  which is  $C_m$ -sequence in  $\bar{D}(w_0, r, r)$ . Thus there exists a closed ball  $\bar{B}(z_0, r) \subseteq P_1(\Omega)$  such that  $\{P_1(f_{n_k})\} = \{(f_{n_k})_1\}$  is a  $C_m$ -sequence in  $\bar{D}(w_0, r, r)$ . Similarly, we can prove it for the sequence  $\{(f_n)_2\}$  in  $F_{e_2} = P_2(F)$ . Therefore,  $F_{e_i} = P_i(F)$  is  $Q_m$ -normal in  $P_i(\Omega)$  for  $i=1,2$  with respect to the chordal metric. Conversely, assume that  $F_{e_i} = P_i(F)$  is  $Q_m$ -normal in  $P_i(\Omega) = \Omega_i$  for  $i=1, 2$  with respect to the chordal metric. we need to show that  $F$  is  $Q_m$ -normal in  $\Omega$  with respect to the bicomplex chordal metric. Let  $\{f_n\}$  be any sequence in  $F$  and  $K$  be any compact subset of  $\Omega$ . Then  $\{P_1(f_n)\} = \{(f_n)_1\}$  and  $\{P_2(f_n)\} = \{(f_n)_2\}$  are sequences in  $F_{e_1} = P_1(F)$  and  $F_{e_2} = P_2(F)$  respectively. Since  $F_{e_1} = P_1(F)$  is  $Q_m$ -normal in  $P_1(\Omega)$ ,  $\{(f_n)_1\}$  has a subsequence  $\{(f_{n_k})_1\}$  which is a  $C_m$ -sequence on compact subsets of  $P_1(K) = K_1$ . Similarly, for the sequence  $\{P_2(f_n)\} = \{(f_n)_2\}$  in  $F_{e_2} = P_2(F)$  and by assumption that  $F_{e_2} = P_2(F)$  is  $Q_m$ -normal in  $P_2(K)$ . Therefore,  $\{(f_n)_2\}$  has a subsequence  $\{(f_{n_k})_2\}$  which is a  $C_0$ -sequence on compact subsets of  $P_2(K)$ . This implies that  $\{(f_{n_k})_1 e_1 + (f_{n_k})_2 e_2\}$  is a subsequence of  $\{f_n\}$  which is a  $C_m$ -sequence in  $P_1(K) \times P_2(K) \supseteq K$ . Thus  $F$  is  $Q_m$ -normal with respect to the bicomplex chordal metric.

**Definition 3.13 :** Let  $S = \{f_n\}$  be a sequence of bicomplex meromorphic functions in a domain  $\Omega$ , and  $Z_0$  a point of  $\Omega$ . We say that  $Z_0$  is a  $\mu_1$ -point of  $S$  if for each closed neighborhood

$\bar{D}(Z_0, r_1, r_2) = \{||Z - Z_0|| \leq r, r = \min(r_1, r_2)\} \subseteq \Omega$ , we have  $\lim_{n \rightarrow +\infty} \max_{Z \in \bar{D}} \partial(Z, f_n) = +\infty$ ,

$Z_0$  is called a  $\mu_2$ -point of  $S$ , if for each open disc  $D(Z_0, r_1, r_2) = \{||Z - Z_0|| < r\} \subseteq \Omega$ ,  $S$  has a  $\mu_1$ -point  $z'$  in the domain  $\{0 < ||Z - Z_0|| < r\}$ . In general,  $m \geq 2$ ,  $Z_0$  is called a  $\mu_m$ -point of  $S$ , if for each domain

$D(Z_0, r_1, r_2) = \{||Z - Z_0|| < r\} \subseteq \Omega$ ,  $S$  has a  $\mu_{m-1}$ -point in the domain  $\{0 < ||Z - Z_0|| < r, r = \min(r_1, r_2)\}$ . Let  $S'$  be a subsequence of  $S$ . Then clearly, if  $Z_0$  is a  $\mu_1$ -point of  $S$ , then  $Z_0$  is a  $\mu_1$ -point of  $S'$ . By mathematical induction, we see that in general,  $m \geq 1$  being an integer, if  $Z_0$  is  $\mu_m$ -point of  $S$ , then  $Z_0$  is  $\mu_m$ -point of  $S'$

Consider the sequence  $S = \{f_n(Z)\}$  defined as follows:

$f_n(Z) = \frac{1}{(Z-n)^2}$ , where  $Z = (z_1, z_2)$  is a point in the bicomplex plane  $\mathbb{C}^2$  and  $n \in \mathbb{N}$ .

Then  $Z_0 = (0,0)$  is a  $\mu_1$ -point of  $S$ ,  $Z_0 = (1,1)$  is a  $\mu_2$ -point of  $S$  and  $Z_0 = (m, m)$  is a  $\mu_m$ -point of  $S$

1.  $\mu_1$ -point: Suppose  $Z_0 = (0,0)$ , and consider a closed disc  $\bar{D} = \{Z \in \Omega: ||Z - Z_0|| \leq r\}$ . For any  $r > 0$ , as  $n \rightarrow \infty$ , the function  $f_n(Z)$  grows unbounded as  $||Z - Z_0|| \rightarrow r$ . Therefore,  $Z_0$  is a  $\mu_1$ -point of  $S$ .

2.  $\mu_2$ -point: Now consider  $Z_0 = (1,1)$ , and a disc  $\Delta = \{Z \in \Omega: ||Z - Z_0|| < r\}$ . In this case, for any  $r > 0$ , there exists a  $\mu_1$ -point  $Z'$  such that  $0 < ||Z' - Z_0|| < r$ , because  $f_n(Z)$  grows unbounded as  $Z \rightarrow Z_0$ . Therefore,  $Z_0$  is a  $\mu_2$ -point of  $S$ .

3.  $\mu_m$ -point: For  $m \geq 3$ , consider  $Z_0 = (m, m)$ . For any disc  $\Delta = \{Z \in \Omega: ||Z - Z_0|| < r\}$ , there exists a  $\mu_{m-1}$ -point  $Z'$  such that  $0 < ||Z' - Z_0|| < r$ . Hence,  $Z_0$  is a  $\mu_m$ -point of  $S$ .

**Definition 3.14 :** Let  $m \geq 1$  be an integer. Let  $F$  be a family of bicomplex meromorphic functions defined on a domain  $\Omega$  and  $\nu \geq 0$  an integer. We say that  $F$  is  $Q_m$ -normal of order  $\nu$  if from every sequence of functions of the family  $F$ . We can extract a subsequence which is a  $C_m$ -sequence in  $D$  and has at most  $\nu$  non  $C_{m-1}$ -point in  $D$ . Thus for  $\nu = 0$ ,  $F$  is  $Q_{m-1}$ -normal in  $D$

**Definition 3.15:**  $Q_m$ -Normal family of infinite order.

A family  $F$  is said to be  $Q_m$ -Normal of infinite order if  $F$  is  $Q_m$ -Normal but not a  $Q_m$ -Normal family of order at most  $\nu \geq 1$ . on this definition we have the theorem:

**Theorem 3.16:** A family  $F$  of bicomplex meromorphic functions is  $Q_m$ -Normal in  $\Omega$  if and only if every sequence of functions  $\{f_n\}$  of  $F$  has no  $\mu_{m+1}$ -point in  $\Omega$ .

**Proof:** Suppose  $F$  is  $Q_m$ -normal in  $\Omega$ . then, by definition, from every sequence of functions  $\{f_n\}$  of  $F$ , we can extract a subsequence which is a  $C_m$ -sequence in  $\Omega$ . We shall prove it by contradiction. Suppose that there exists a  $\mu_{m+1}$ -point  $Z_0$  of some sequence  $\{f_n\}$  in  $F$ , i.e., for every open disc  $D(Z_0, r_1, r_2)$  contained in  $\Omega$ , there exists a  $\mu_m$ -point  $z'$  in the domain  $\{0 < ||Z - Z_0|| < r\}$ . This implies that we can construct a subsequence of  $\{f_n\}$  that converges to  $+\infty$  at  $Z_0$ , which contradicts the assumption that  $F$  is  $Q_m$ -normal. Therefore,  $F$  cannot have a  $\mu_{m+1}$ -point in  $\Omega$ . Suppose  $F$  is  $Q_m$ -normal in  $\Omega$ .

By definition, this means that from every sequence of functions  $\{f_n\}$  of  $F$ , we can extract a subsequence which is a  $C_m$ -sequence in  $\Omega$ . To prove this statement, we shall use proof by contradiction. We assume that there exists a  $\mu_{m+1}$ -point  $Z_0$  of some sequence  $\{f_n\}$  in  $F$ . This implies that for every open disc  $D(Z_0, r_1, r_2)$  contained in  $\Omega$ , there exists a  $\mu_m$ -point  $z'$  in the domain  $\{0 < ||Z - Z_0|| < r\}$ . Now, consider a sequence  $\{f_n\}$  in  $F$  and let  $Z_0$  be a  $\mu_{m+1}$ -point of this sequence. For any open disc  $D(Z_0, r_1, r_2)$  contained in  $\Omega$ , there exists a  $\mu_m$ -point  $z'$  in the domain  $\{0 < ||Z - Z_0|| < r\}$ . This implies that we can construct a subsequence of  $\{f_n\}$  that converges to  $+\infty$  at  $Z_0$ , which contradicts the assumption that  $F$  is  $Q_m$ -normal. If  $F$  were  $Q_m$ -normal, there should be no such  $\mu_{m+1}$ -point. Therefore, we have shown that  $F$  cannot have a  $\mu_{m+1}$ -point in  $\Omega$ . In summary, we have demonstrated that if  $F$  is  $Q_m$ -normal in  $\Omega$ , then it cannot have a  $\mu_{m+1}$ -point in  $\Omega$ . To prove the converse part, let's assume that  $F$  does not have any  $\mu_{m+1}$ -point in  $\Omega$ . We aim to show that  $F$  is  $Q_m$ -normal in  $\Omega$ . Let  $\{f_n\}$  be any sequence of functions in  $F$ . Since  $\{f_n\}$  has no  $\mu_{m+1}$ -point in  $\Omega$ , it means that for every sequence  $\{Z_k\}$  in  $\Omega$ , there exists a subsequence  $\{f_{n_k}\}$  of  $\{f_n\}$  such that  $\lim_{k \rightarrow \infty} f_{n_k}(Z_k) = +\infty$ . This implies that for any closed disc  $\bar{D}(Z_0, r_1, r_2)$  contained in  $\Omega$ , we can find a subsequence of  $\{f_n\}$ , denoted by  $\{f_{n_k}\}$ , such that  $f_{n_k}(Z_k)$  diverges to  $+\infty$  as  $k$  approaches infinity, where  $Z_k$  is a sequence of points in  $D(Z_0, r_1, r_2)$ . Therefore,  $\{f_n\}$  satisfies the condition of being a  $C_m$ -sequence. Since this holds for any sequence  $\{f_n\}$  in  $F$ , it follows that  $F$  is  $Q_m$ -normal in  $\Omega$ . Therefore, we have shown that a family  $F$  of bicomplex meromorphic functions is  $Q_m$ -normal in  $\Omega$  if and only if every sequence of functions  $\{f_n\}$  of  $F$  has no  $\mu_{m+1}$ -point in  $\Omega$ .

## 4. Conclusion

This paper extends the theory of  $Q_m$ -normal families of meromorphic functions using the concept of  $C_m$ -sequences from the complex variable setting to the bicomplex variable setting. It begins with a discussion of the properties of bicomplex meromorphic functions and establishes its key results in the bicomplex plane. Using  $C_m$ -sequences, the concept of  $Q_m$ -normal families is generalized to bicomplex meromorphic functions, offering new insights and a broader scope for understanding normality in this richer setting. This study highlights  $Q_m$ -normal families of bicomplex meromorphic functions as a specialized and emerging area in bicomplex analysis. It provides a foundation for future research into deeper theoretical aspects, including their properties, characterizations, and connections with other mathematical structures. Furthermore, this research encourages exploration into how the behaviors of  $Q_m$ -normal families in the bicomplex domain differ from those in the complex domain, necessitating the development of new theoretical frameworks. Additionally, such families have the potential to model physical phenomena in multi-dimensional spaces, making them relevant for applications in fields like quantum mechanics and relativity theory. The results presented in this paper pave the way for further studies, contributing to both the theoretical and applied dimensions of bicomplex analysis.

## Acknowledgements

Authors are thankful to the Department of Mathematics, Bhagwant University for giving us this opportunity. Authors are also thankful to Dr. Muzafar Ahmad Bhat, Lecturer, Department of Sericulture, Government Degree College Poonch, University of Jammu for his constant technical support.

## Author Contributions

All authors contributed in the concept and design of the present study. Material preparation, data collection and analysis performed by [Tehseen Abas Khan], [Jyoti Gupta] and [Ravinder Kumar]. The first draft of the manuscript was written by [Tehseen Abas Khan] and all authors read and approved the final manuscript. As the field progressed, researchers like Giovanni Battista Rizza and Marcel Riesz made substantial contributions to the study of bicomplex functions and their analytical properties in the mid-20th century. Their work paved the way for deeper explorations into the analytical aspects of bicomplex analysis.
